A

Aaron, Dr. C. D., Diseases of the Stomach, with Special Reference to Treatment, 1911 (review), 1691
Abderhalden, Prof. E., Fortschritte der Naturwissenschaften Forschung, herausgegeben von (Investigations in Natural Science), 1911) review, 29—Physiologisches Praktikum Chemische und Physikalische Methoden, 1912 (review), 1692
"Abdomen, acute," two cases of, 722; tumour in, case of, 928
Abdominal drainage in treatment of peritonitis (Mr. C. Wallace), 903; abdominal operations, major, early rising after, 1650; rigidity under anæsthesia, prevention of, 1690
Abdominal Organs, Malignant New Growths of (Interne Klinik der bösartigen Neubildungen der Bauchorgane) (Dr. R. Schmidt) (review), 512; pain as premonitory sign of diabetic coma, 378; section for localised suppurative puerperal peritonitis, right oöphoritis, cellulitis, slight salpingitis, 1201; twice on same patient for acute intestinal obstruction due to volvulus, 430; support, new, 658; wall, cold abscess of, 42, 431
Abercrombie, Dr. R., treatment by means of mechanical therapeutics at the Edgar Allen Institute, Sheffield, 1076
Aberdare Isolation Hospital, 69
Aberdeen, action of chemists and druggists of, concerning closing order, 1028; city of, annual report of medical officer of health, 1220; festivities in, in honour of Mr. Carnegie, 1649; medical inspection of school children in, 462; medical men of, and National Insurance Act, 759; notification of measles in, 463; organisation of charities, 116; practitioners of, and National Insurance Act, 1441; sanatorium for, suggested, 957; Tuberculosis Exhibition at, 957; University of, pass-lists, 962; (see also Marischal College); war against consumption in, 262
Aberdeen Dispensary and Maternity Hospital, 1574
Aberdeen Royal Asylum, fire at, 759
Aberdeen Royal Infirmary, 7[illegible]; bequest for, 1436; death of matron of, 198; Hospital Sunday collections for, 19[illegible]; and asylum managers, 198
Aberdeenshire, consumption in, 1372; sanatorium treatment in, 1789
Abergele, South Manchester guardians' sanatorium at, 1093
Abolition of Vivisection Bill, 620
Abor expedition, 1783
Abraham, Dr. P. S., discussion on bubonic plague, 366
Abrahams, Dr. A., athletics, 327
Abram, Dr. J. H., two cases of œdema of the orbit, 435
Abscess, cold, of abdominal wall, 42, 431
Abscess-formation, fate of appendix after, 535; (Mr. A. P. Dodds-Parker), 360
Abscesses, sterile, following use of tuberculin (Dr. D. Forbes and Dr. C. Banks), 1338
Academy of Medicine, Paris, 1438; election at, 835; Academy of Medicine, Toronto, Lister night at, 1439
Academy of Sciences, Paris, election at, 835
Accident, remarkable, from revolver shot, 1375; and injury, relationship of tuberculosis to (Dr. W. C. Bosanquet), 75, 110; to hospital nurse, responsibility for, 128; insurance, sickness, and, 617; insurance and medical profession in France, 124
Accidents, First Aid in (Sir J. Collie and Mr. C. F. Wightman) (review), 1698; industrial, notice of international congress on, 1146; railroad, increase of, in United States, 200; (see Street accidents)
Accountant, independent, for medical men on question of National Insurance Act, appointment of, 1794
Acetone-Wright method of leucocyte counting, 389
Acetonuria, significance of, in children, 433
Achlorhydria, lineæ atrophicæ, and typhoid fever, case of (Mr. J. C. D. F. Vaughan), 1404
Achylia (hysterical vomiting), case of, 580
Acidosis in pregnancy, clinical significance of, 1340
Ackerley, Dr. R., discussion on radium emanations of mineral waters, 1200; health season in Egypt, 56; the medical profession and the National Insurance Act, 458
Acquisitiveness in general paralysis of the insane, 275
Acrodermia neuritica, case of, 509
Acromegaly, absence of, in disease of pituitary body, 1410; personal experience of (Dr. L. P. Mark) (review), 995
Acromegaly (?), case of, 1535, 1614
Acromion process, separate, 1616; and upper end of humerus, appearances presented by, during ossification, 1616
Actinomyces, cultures and slides of, 112; human, 1132
Adami, Prof. J. G., American Order of Merit suggested by, 1096; appointment to, 761; presidential address at twelfth annual meeting of Canadian Association for the Prevention of Tuberculosis, 1570
Adams, Dr. A., case of ruptured kidney, 861
Adamson, Dr. H. G., Goulstonian lectures on modern views upon the significance of skin eruptions, delivered before the Royal College of Physicians of London, 911, 969, 1041
Addison, Mr. O. L., bony growth on the skull, 1199; exostosis of the inner end of the clavicle, 1199
Addison's disease, clinical history and morbid anatomy of case of, 366; value of suprarenal extract in, 1343
Adelaide Hospital, 1793
Adenitis, chronic simple, 343; of doubtful nature, with malignant developments, 345; syphilitic, 344; tuberculous, 343
Adenoids, recurrence of, 299; (Mr T. J. Guthrie) 1054
Adenoma, fibro-cystic, of thyroid gland, 929
Adie, Mr. H. A., sex of the larvæ of mosquitoes and other experimental work, 865
Adkins, Mr. G., recent outbreak of poliomyelitis at Stoke Rivers, 607
Admiralty tests for colour blindness 1 9, 1092, 1154
Adrenalin in cardiac debility and dilatation, 1182; oral administration of small doses of, in treatment of whooping-cough, 1343; and pituitrinum, influence of, upon respiratory metabolism, 1788
Adrenin, disappearance of skin carcinoma under local application of (Mr. L. C. P. Ritchie), 1754
Adult, treatment of gonorrhœal conjunctivitis in (Mr. J. S. Horsford and Mr. G. B. James), 91
Adulteration of flour (Parliamentary question), 842, 905; of food, 198
Advisory Committee, Irish meeting of, 1506; National Insurance Act, medical representatives, 1031
Aeronautics, military, in France, 1308
Æsculape (review), 879, 176

89-50
.558
9/2, v.1, pt.1
707403
(RECAP)

Afferent impulses, three main divisions of, 2; in spinal cord and brain stem, grouping of, 1
Africa, Continent of, Climate (Mr. A. Knox) (review), 174; East, Protectorate of, vital statistics, 625; Prevention of tropical diseases in, 1217; South, coast of, sanitation needed for whaling stations on, 401; mine-dust problem in, 242

AFRICA, SOUTH, CORRESPONDENCE FROM.—South African Memorial to King Edward VII.; Proposed hospital legislation; Friction at the Johannesburg Hospital; Ward *v.* Hertzog; The late Sir Charles O'Grady Gubbins, 65—Defence Bill; Town Planning Bill; Conference of Government health officers; Obituary, 66—Squatter's Bill; White nurses for natives; Rabies in Rhodesia; Whaling on the South African Coast; Death of Mr. H. C. Keilly-Flynn; Sanatorium for miners' phthisis; South African Medical Congress (1912), 400, 401—Medical legislation; Treatment of lunatics; Closure of the Sydenham Asylum; Rand water shortage; Proposal to establish a municipal dairy at Bloemfontein; Plague at Durban, 693—Small-pox in Johannesburg; Anthrax on the East Rand, 694—Public health legislation, 1027—Prevention of tuberculosis; Non-publication of vital statistics; Plague at Durban; Weights and Measures Bill, 1028—Mortality among mine employees, 1163—Thirteenth South African Medical Congress; Death registration; Lay vaccination; Leprosy in Basutoland; Cape hospital ordinance; Public Health Bill; Report of the Miners' Phthisis Commission, 1651, 1652

Africa, South, prevalence of syphilis in natives of, influence of, in aiding spread of tuberculosis (Mr. B. G. Brock), 1270; risk of sending phthisical patients to ("ordered South"), 1720; West, health of Europeans in (Dr. A. E. Horn), 1356; invalidity and death-rates of non-native officials of, 951
Africa, Tropical, How to Live in, Guide to Tropical Hygiene and Sanitation (Dr. J. Murray) (review), 1621
After-care Association, 1310; for Poor Persons discharged recovered from asylums for the insane, 697; of sanatorium patients, 1784
Anchylostoma Duodenale, Anatomy and Life History of (Records of the School of Medicine, Cairo, Vol. IV.) (Prof. A. Looss) (review), 876; (see also Ankylostoma)
Agents, Physical, Formula of (Formulaire des Agents Physiques) (Dr. J. Larat and others) (review), 304
Agglutination tests in paratyphoid fever and meat poisoning, 705
Aggressins, Problems of, Pathology of Immunity with Regard to (Mr. L. S. Dudgeon) (review), 1593, 1671, 1737
Agra and Oudh, medical services in, 1727
Agricultural Research and University of Bristol, 614
Agricultural and village population, prophylaxis of tuberculosis among, 1095
Air, chemical purity of, 451; compressed, rupture of bowel due to injection of, 1704; concentration of carbon dioxide in, 451; concentration of oxygen in, 451; embolism, 1369; ozonised, in tube railways, 1353; supposed presence of organic poisons in, 452; (see also Safety Air)
Air-pump, electrically driven, 1171
Alaska, mortality among Indians of, 838
"Albar" breathing apparatus, 409
Albarran, Prof., obituary, 330
Albumin-reaction of sputum in pulmonary tuberculosis, 309
Albuminuria accompanying diabetic gangrene, 349; influence of, upon hearing, 1650
Alcohol, consumption of, in Paris, 1307; effect of, on spread of tuberculosis, 1304; injection of Gasserian ganglion for trigeminal neuralgia (Dr. W. Harris), 218; Modern Medical Opinions on (review), 31; percentage of, found in stomach, question of, 271; therapeutic value of, discussion on, 1058, 1274
Alcoholism, struggle against, 900
Aldershot, hospitals, Royal visit to, 1398
Alderson, Dr. W. E., and Bolam Mr. J., Dental Anæsthetics: a Text-book for Students and Practitioners, 1911 (review), 511
Ale, English, comparatively sugar-free, 1282
Aleppo, cholera in, 464
Alexander, Dr. G. F., and Campbell, Mr. E. K., the operative treatment of concomitant strabismus, 1466
Alexander, Dr. J. F., treatment of burns, 110
Aliens, insanity among, in United States, 1096
Alienists and neurologists, French, congress of, 128
Allantoin, new-cell proliferant, 870
Allbutt, Sir T. C., nomenclature of disease, 808, 1017; the physician and the pathologist on heart failure, 743, 795
Allchin, Sir W. H., death of, 447; obituary, 544
Allen, Mr. C. H., sarcoma of the thigh, 799
Allen, Prof. H. B., dinner to, 1030
Allen's Commercial Organic Analysis, 1911 (review), 171
Allsop, Mr. R. O., Engineering Work in Public Buildings (review), 1694
Alps, accidents in, during 1911, 265
Altitude, influence of, in treatment of pulmonary tuberculosis (Prof. Chr. Saugman), 1127
Aluminium apparatus for fractures of limbs, 760
Ambulance lectures, lantern slides wanted for, 553; service for London, 1363
Ambulances, municipal, in Paris, 1094
America, States, Various Digest of Laws and Regulations of, relating to Reporting of Cases of Sickness (Assistant Surg.-Gen. J. W. Trask) (review), 878
American Episcopal Church, attitude towards eugenics, 1097
American Exhibition of Hygiene, 1093
American Medicine, Triumph of, in Construction of Panama Canal, 1911 (Dr. J. E. Mears) (review), 373
American Order of Merit, suggested, 1096
American Proctologic Society, 1309
Americanists, International Congress of, 1582
Americans, native-born, decreasing birth-rate among, 1237
Amœbæ, Parasitic, of Man (Dr. C. F. Craig) (review), 652
Amœbic dysentery contracted in Scotland, 1145
Ampoules and globules, new, 999
Amputation for diabetic gangrene, cause of death after, 350; of fingers, case of, 98
Anæsthesia, apparatus for producing, 1277; ether infusion, 794; general, by Schleich's method, 1026; hedonal infusion, 794; local, herniotomy under, followed by acute dilatation of stomach, 1004; partial thyroidectomy for, with special reference to exophthalmic goitre (Dr. T. P. Dunhill), 422; need of preparation for, 232; pioneer of, Dr. C. W. Long, (Dr. D. W. Buxton), 669, 816; (leading article), 660; post-anæsthetic poisoning, 1130; prevention of abdominal rigidity under, 1690; spinal enterectomy under, for acute intestinal obstruction in infant 24 hours old, survival for one month (Mr. G. E. Waugh), 427; vital phenomena occurring under, nervous circulatory, respiratory, and metabolic, relation of, to safety of patient (Dr. D. W. Buxton), 1267; (see also Nitrous oxide and oxygen anæsthesia)
Anæsthesia and Analgesia (Dr. J. D. Mortimer) (review), 1137
Anæsthetic, general, hedonal administered by intravenous infusion, 1568
Anæsthetics, Dental (Dr. W. E. Alderson and Mr. J. Bolam) (review), 511; general, hedonal as, administered by intravenous infusion, report on 75 cases (Mr. C. M. Page), 1258; Practical (Mr. H. E. G. Boyle) (review), 510
Analgesia and Anæsthesia (Mr. J. D. Mortimer (review), 1137
Analysis, Commercial Organic (Allen's) (review), 171; Elementary Quantitative (Mr. F. M. Oldham) (review), 806; Organic, Handbook of (Mr. H. T. Clarke (review), 806
Analyst, public, pay of, 663; for Wandsworth, 930

ANALYTICAL RECORDS FROM THE LANCET LABORATORY.—Bismosal, 1766—Collosol Silver and Collosol Mercury, 307—Decodol, 657—Digalen Tablets, 999—Digipuratum (Knoll), 1548—Dry Diamalt, 306—Ecsolent Compounds, 1283—English Ale (Comparatively Sugar-free), 1282—Eucerin, 657—Euresol pro capillis, 1283—(1) Ferrosajodin; and (2) Tuberculin A. F. (Albumose-free Tuberculin), 33—Genuine Hollands (de Kuyper's), 32—India pale ale, 1548—Invalid stout, 999—(1) Iodostem; and (2) Stem, 32—Jaeger Sardines, 307—Joha (Salvarsan), 307—Junora, 657—Larbose, 1282—Martha-Quelle Mineral Water, 1283—Merjodin, 1767—Melubrin, 1766—Nephritin, 1548—New Ampoules and Globules, 999—Nonac port wine, 1548—Novoform (Hayden), 33—Olival Soap, 999—(1) Patent Barley; and (2) Patent Groats, 657—Plasmon Biscuits, 1283—Poultogen, 307—Protein Food with Organic Phosphates, 658—Reagents for Use in the Wassermann Syphilis Reaction, 32—Ridge's desiccated milk, 1548—Scotch Whisky (the Hunting Squire Brand), 33—(1) Special Oil Silk; and (2) Waterproof Sheeting, 657—(1) "Tabloid" Hypodermic Ergamine; (2) "Tabloid" Ophthalmic Physostigmine Salicylate; (3) "Tabloid" Ophthalmic Pilocarpine nitrate, 1766—Thiccol, 307—Various Bottled Fruits, 33—Wines for Invalid Use, 1767—Zone salt, 1548

Anaphylactic sh[ock], treatment of, 1567, 1643
Anaphylatotoxin [and] Anaphylatoxin, Bacterial), Das Bakterien- 912 (Dr. H. Dold) (review), 1619
Anaphylaxis, dr[ug] to, 972; path[ology] sensitiveness, eruptions in relationship ogy of, 1419; or hyper- octrine of, applied to skin diseases, 971
Anastomosis, ar[terio]-venous, surgical emergencies in, 144 [spinal] acio-hypoglossal, 584
Anatolia (Turke[y]) malaria and syphilis in, 1503
Anatomical Soc[iety] of Great Britain and Ireland, summ[er] meeting of, 1771
Anatomy, Applied, and Oral Surgery for Dental Students (Mr. R. H. Ivy), (review) 590; new inspection of, for Ireland, 1725; Pathological, General, and Special: Pathologische Anatomie, Band i., ii., 1911 (Prof. L. Aschoff and others) (review), 367; Practical, 2 vols., 1912 (Mr. F. G. Parsons and Mr. W. Wright) (review), 1063; Surface, Essentials of, second edition, 1911 (Mr. C. R. Whittaker) (review), 371; teaching of (leading article), 517
Anders, Dr. J. A., and Dr. L. N. Boston, Textbook of Medical Diagnosis (review), 1136
Anderson, Mr. A. R., obturator hernia, 1060
Anderson, Prof. H. B., recurring hæmoptysis due to a small aortic aneurysm, 1355
Anderson, Dr. H. M., note on an unusual case of inguinal hernia, 503
Anderson, Dr. J. R. S., insomnia, 1277
Anderson, Dr. W. M. A., M.V.O., honour of knighthood [con]ferred on, 666
Andrew, Dr. note on a case of fracture of the larynx, [1]
Aneurysm, ab[dominal], 729; aortic, in women, 928; of first part of aorta, diastolic shock and diastolic thrill over heart, 1537; mistaken for asthma, 597; small, causing recurring hæmoptysis, 1355; present treatment of (leading article), 1481; surgical treatment of, 406; thoracic, not connected with aorta, [con]-co-arctation of aorta, 1535; treatment by endoaneurysmorrhaphy in British Isles, details of 16 cases, 1400; surgical (Mr. H. G. Barling), 1399; in region of cœliac axis two cases operated on for, 583
Aneurysms, multiple embolic, of pulmonary arteries, case of, 579; popliteal, Hunter's work on, 140; subclavian, surgical emergencies in, 144
Angers, disturbances at, 263
Angina abdominalis, 1368, 1432, 1495, 1565; case of (Sir L. Brunton and Mr. W. E. Williams), 921. 926; Vincent's, destruction of uvula in, 1199
Angior, Mr. F. L., value of suprarenal extract in Addison's disease, 1343
Anglo-Indians and Indians, Tropical Hygiene for (Hon. Surg.-Gen. C. P. Lukis and Maj. R. J. Blackham) (review), 173
Animals, Breeding of, Heredity in Relation to (Prof. W. E. Castle) (review), 805; Domestic, Bacteria, Yeasts, Molds, and Protozoa Pathogenic for (Prof. R. E. Buchanan) (review), 172; tuberculosis in, in relation to tuberculosis in man, 131; hibernating, observations on heart movements of, by means of electrocardiograms, 866; living, experiments on (Parliamentary question), 1246; prevention of cruelty to, 1305
Ankle, tuberculous, operation on, 6
Ankylosis, Cæsarean section in primipara suffering from, 1276
Ankylostoma caninum, blood-volume in, 927
Annals of Tropical Medicine and Parasitology (review), 1470
Annam, sale of quinine in, 329
Annual Report for 1911 of the Royal Dental Hospital for London, 1912 (review), 1546
Anæmia, pernicious, artificial production of, 1708
Anoxyhæmia [from] altitude, treatment of, by subcutaneous oxygenation, 1726
Anthracoid org[anism], cellulitis of leg due to, 97
Anthrax, action of salvarsan in, 692; case of (Parliamentary question), 698; detection of, in industrial material, 799; (Parliamentary question), 6[98]; precautions against, 1026; prevalence of (Parliamentary question), 560; in East Ran[ges], 394
Anthropoids, [in]stinct, 776; modern, and man, 776
Anthropologic[al] Museum, Marischal College, Aberdeen, [Re]port; of the University of Aberdeen, [Cat]alogue of, 1912 (review), 1622
Anthropology, [Fa]ir of, proposed, for Melbourne Uni[ver]sity, 129; dream of, 519; Practical (Mr. [C.] E. Smurthwaite) (review), 931; and [Ar]chæology, Prehistoric, Fourteenth Inter[na]tional Congress of, 1506
Anti-malarial [mea]sures in India, incident in, 762
Anti-plague se[rum], observations on, 529
Anti-rinderpe[st se]rum, 1728
Antiseptics, a[ction] of, vibrations of, 314

Antiseptics, urinary, in cystitis, 684; (Mr. C. Williams), 1335
Antistreptococcus serum in treatment of pyæmia, case of (Mr. C. W. G. Bryan), 501
Anti-tuberculosis crusade, organisation of, 1432
Anti-tuberculosis dispensary at Bristol, 59; exhibition in Birmingham, 1573; therapeutic measures, value of, 1575
Anti-typhoid inoculations, 435; vaccination, 63, 1576
Antivaccination propaganda in United States, 1504; reply to Dr. Copeman's article in Encyclopædia Britannica, 519; tactics in, in India, 244; in Ireland, 1373
Antivaccination Bill, 1075
Antivenomous serum in treatment of scorpion stings in children, 760
Antivivisection exhibition (Parliamentary question), 1658
Anuria, calculous, surgical emergencies in, 142
Anus, Rectum, and Sigmoid, Diseases of (Dr. S. T. Earle) (review), 510
Aorta, abdominal, thrombosis of, and obliterative arteritis in same case, 246; aneurysm of first portion of, diastolic shock and diastolic thrill over heart, 1537; (?) co-arctation of, with thoracic aneurysm not connected with aorta, 1535; congenital stenosis of, 1719; stenosis of, congenital, case of (Dr. R. O. Moon), 1531; thoracic, aneurysm of, X ray diagnosis of, 873; and heart, ortho-roentgenography of, 507; (see also Aneurysm, aortic)
Aortic valves, functional incompetence of, 1176
Aortitis, syphilitic, with valvular incompetency (Dr. A. Morison), 287
Aphasia, recurrent, with high blood pressure, case of, 164
Aphonia, functional, in child aged 6, unusual case of, 649
Apocrypha, miracle in, explained, 661
Apothecaries' assistants, registration of (Parliamentary question), 904
Apothecaries' Hall, Dublin, and preliminary examination, 1626
Apparatus, improved, for administration of hedonal, 1631; for producing anæsthesia, 1277
"Appeal for a strong but moderate policy," circular letter in reference to National Insurance Act, 473
Appelt, Mr. A., The Real Cause of Stammering and its Permanent Cure; A Treatise on Psycho-analytical lines, 1911 (review), 101
Appendicectomy, calcareous mass found during, 1696
Appendicitis, acute, obscured by acute intestinal obstruction caused by appendix vermiformis (Mr. E. Gillespie), 792; surgical emergencies in, 141; treatment of, when and how to operate (Sir G. T. Beatson), 1253; onset of diabetic coma simulated by, case of, 647; time to operate in, 1352; trauma as cause of, references to literature required, 71; and dysentery, relations between, 691, 692
Appendix, acute intestinal obstruction caused by, the obstruction obscuring acute appendicitis (Dr. E. Gillespie), 792; causing acute intestinal obstruction, 954; carcinoma of, case of, 1755; fate of, after abscess formation, 456, 457, 535; (Mr. A. P. Dodds-Parker), 360; inflamed, morbid conditions in structures around, 1253; inflammation of, primary causes, 1253; and tonsils, functions of (Mr. K. H. Digby), 160; streptococcal infections of, 1520
Apperly, Mr. R. E., investigations into after-effects of chloroform, 434
Appliances (invalid and "comfort"), 1799

Gloucester, county of, annual report of medical officer of health, 253
Gloucestershire Royal Infirmary, annual meeting, 1102
Glucose, excretion of, in myxœdema, 631; limit of tolerance of, 487; lowering of tolerance, significance of, 488
Glycosuria (Dr. A. E. Garrod), 483, 557, 629; adrenal, 632; and pituitary body, 631; and thyroid gland, 629; classification of varieties of, 485; diagnosis of, 484; Die Ursachen der Glykurie, 1911 (Dr. F. Rosenberger) (review), 1279; historical sketch of, 483; in pregnancy, 633; induced by thyroid administration, 630; potential or alimentary, 487; temporary or transient, 557; without hyperglycæmia, 633
Glynn, Dr. E. E., detection of anthrax in industrial material, 799; and Dr. G. L. Cox, and Mr. F. C. Lewis, bacteria carried by flies in City of Liverpool, 1131
Goats, population of, in Malta, and relationship of to incidence of Mediterranean fever in (Prof. J. W. H. Eyre), 88
Godfrey, Dr. H. W., local reaction in tuberculin treatment, 194
Godlee, Sir R. J., and Barlow, Sir T., dinner to, 447
Godwin, Dr. H. J., the fate of the appendix after abscess formation, 457
Goethe, condition of eyes of, 1486
Goitre endemic, in Tyrol, clinical observations on, 1708; etiology of, 128; exophthalmic, 680; discussion on, 503, 576, 724; partial thyroidectomy under local anæsthesia for (Dr. T. P. Dunhill), 422; pathology and treatment of, 608; principles of treatment of (Prof. G. R. Murray), 489; surgical treatment of, 576; parenchymatous, in man aged 60, 731; simple, treatment by vaccines (Capt. R. McCarrison), 357, 364
Goldmann, Prof. Dr. E. E., cellular activity in health and disease, chemical studies based on new methods of intra-vitam staining, 1183; (leading article), 1208; Die äussere und innere Sekretion des gesunden und kranken Organismus in Lichte der "Vitalen Farbung," 1909 (review), 1203; Neue Untersuchungen über die äussere und innere Sekretion des gesunden und kranken Organismus, 1912 (review), 1203; Studien zur Biologie der bösartigen Neubildungen, 1911 (review), 1203
Goldzieher, Dr. W., treatment of gonorrhœal conjunctivitis with steam, 597
Golf, medical, at Bristol, 1708
Golightly, Mr. H. E., League of Mercy, 1661
Gonococcus infections, chronic, diagnosis of, 1133
Goodall, Dr. A., acute myelocythæmia associated with osteosclerosis and other unusual features, 1275; Aids to Histology, 1912 (review), 237
Goodall, Dr. E., intestinal flora, 684; psychiatry in England, its present state and outlook, 1089
Goodall, Dr. E. W., discussion on therapeutic value of alcohol, 1274
Goodhart, Dr. G. W., discussion on chloroform poisoning, 434
Gordinier, Dr. H. C., occlusion of the posterior inferior cerebellar artery—a definite symptom-complex, 380
Gordon, Dr. A., the finger phenomenon, a new sign of organic hemiplegia, 312
Gordon, Dr. W., case of cancer of the œsophagus with perforation, 874; value of the cardiac sign in cancer, 874
Gordon, Mr. W. H., and Kennard, Mr. D., salvarsan in syphilis, 862
Gordon Memorial College, Khartoum, fourth report of Wellcome Tropical Research Laboratories at (1911), 1061
Gossage, Dr. A. M., discussion on use of sphygmomanometer in general practice, 1408; family with fibrinous discharge from the nose, 723
Gosset, Prof. A., primary sarcoma of the stomach, 1105
Gottheil, Dr. W. S., blue atrophy of the skin following cocaine injections, 442
Gottlieb, Dr. R., and Meyer, Dr. H. H., Die Experimentelle Pharmakologie als Grundlage der Arzneibehandlung, 1911 (review), 653
Gould, Sir A. P., medical profession and the National Insurance Act, 52; "radical" operation for malignant disease of the testicle, 534
Gould, Dr. G. M., Pocket Medical Dictionary, 1911 (review), 304
Gouley, Dr. J. W. S., Surgery of the Genito-urinary Organs (review), 171
Goulston, Dr. A., award of Hunterian Society's silver medal to, 696
Goulstonian lectures on modern views upon the significance of skin eruptions, delivered before the Royal College of Physicians of London (Dr. H. G. Adamson), 911, 969, 1041
Gourand, Dr. F. X., and Castaigne, Prof. J., Le Livre du Médicin, la Tuberculose, 1912 (review), 1618
Gout, true, case of, 97
"Gouttes de Lait," national conference of, 691
Govan District Asylum, Hawkhead, Paisley, annual report, 1911, 1081
Government College, Lahore, appointment of Maj. J. Stephenson as principal of, 1029
Government of Ireland Bill, university representation under, 1236
Grace Brothers and Co., Ltd., cobra venom, a query, 71
Grancher system of preserving the young from tuberculosis, 1157
Grand Canary, public health in, 536
Grant, Dr. J. Dundas, case of tuberculous laryngitis, 228
Grant, General, experiences with army of, in 1864, 1298
Grants for treatment of tuberculosis (Parliamentary question), 1658

Granuloma, ulcerating, of the pudenda, as found in Government Lock Hospitals, Western Australia (Dr. D. Steel), 225
Graves's disease, operative treatment of (Mr. W. Trotter), 641
Gray, Dr. A. A., changes in the labyrinthine capsule in otosclerosis, 1472
Gray's Hospital, Elgin, 198
Great Britain, amœbic dysentery in, 811; Law relating to Medical Practitioners and Dentists in, with Appendix of Statutes (Mr. J. N. Morton) (review), 512
Greece, rabies in, 1511
Greek inscriptions, ancient medicine revealed by, 593
Green, Dr. A. S., opening of discussion on whether removal of glands in malignant disease was worth while, 650
Greene, Dr. H. M., etiology of epilepsy, 1376
Greenwich College, new Royal Naval Medical School at, 1297
Greenwood, Dr. M., infant mortality, 594; medical profession and National Insurance Act, 192, 393, 1433
Greeves, Mr. R. A., recurrent unpigmented tumour of the sclera, 575
Gresham lectures for 1912, 1129
Griffith, Mr. D. A. H., discussion on melanotic sarcoma of choroid with general metastasis, 1410
Griffith, Dr. T. W., paralysis of the left vocal cord, left half of palate, and left side of face, 1276
Griffith, Dr. W., recent advances in the study of syphilis, opening of discussion, 1474
Griffith, Dr. W. S. A., discussion on relative size of uterus in cases of hydatidiform mole, 227
Griffiths, Dr. F. G., Studies in Pulmonary Tuberculosis, its Dissemination, Specific Diagnosis and Treatment, and some Points in its Pathology, 1911 (review), 1476
Griffiths, Mr. J. G., and Crossley, Sir S., King Edward's Hospital Fund for London, and the Evelina Hospital, 455
Griffiths, Mr. L. M., History of Bristol Medical Library (review), 1348
Groats, patent, 657
Groin, left, enlarged glands in, case of, 799
Grossich, Dr. A., Meine Präparationsmethode des Operationsfeldes mittels Iodtinktur, 1911 (review), 733
Groves, Dr. W. B., intestinal perforation in convalescence from typhoid fever simulated by pneumonia, 1075
Growths, multiple, of great gut, 793
Gruber, Prof. M. v., and Rüdin, Dr. E., Fortpflanzung, Vererbung, Rassenhygiene, Katalog der Gruppe Rassenhygiene der Internationalen Hygiene-Ausstellung 1911 in Dresden (review), 589
Grünbaum, Prof. A. S., and Cattley, Dr. R., genesis of chronic arteritis, 651
Grünbaum, Drs. H. G. and A. S., further experiments on the treatment of inoculated rat sarcoma and observations on certain accompanying blood changes, 644
Grünbaum, Dr. O., hæmo-renal index, 1339
Guayaquil, pest hole of Pacific, 812
Gubbins, Sir C. O'Grady, obituary, 65
Guernsey, non-tuberculous milk in, 258
Guiana, British, vital statistics of, 135
Guide to the Income Tax, 1912 (review), 1281
Guido Baccelli Ambulance at Tripoli, 837
Guildford, borough of, annual report of medical officer of health, 1221; report of school medical officer of, 1710
Guillotine for tonsil enucleation, 1206
Guiteras, Dr. R., Urology, the Diseases of the Urinary Tract in Men and Women, a Book for Practitioners and Students, 1912 (review), 1763
Gulland, Dr. G. L., case of myxœdema, 506; of tabes dorsalis, 506; discussion on vaccine therapy, 230
Gullet, malignant stricture of, radium salts in, 433
Gum, chewing of, in American navy, probibition of, 543
Gumma of lung, 1200
Gunn, Mr. K. E. L. G., discussion on venovenostomy in ascites, 24; two specimens from cases of disease of the bladder, 366
Gunson, Dr. E. B., case of hæmopericardium of traumatic origin, operation, 1533
Gunshot wound of pregnant uterus, 1213
Gut, great, multiple growths of, 793
Guthrie, Dr. L. G., case of transposition of the viscera, 580; chronic jaundice and splenomegaly in a girl 6 years of age, 927; discussion on acute poliomyelitis and allied conditions, 652
Guthrie, Mr. T., discussion on rational treatment of chronic suppurative otitis media, 167; guillotine for tonsil enucleation, 1206; recurrence of adenoids, 299, 1054
Guttate iritis, 505
Guy, Mr. W., discussion on care of the teeth at school age, 1615
Guy's Hospital, visit to, of American surgeon (Dr. W. J. Mayo), 1536
Gymnastics, Medical, for Treatment of Disease, Deformity, and Injury (Mr. F. F. Middleweek) (review), 931
Gynæcological Practice, Directions and Prescriptions for (Arznei- und Diätverordnungen für die Gynækologische Praxis), 1912 (Prof. P. Strassmann) (review), 1348
Gynæcology, classification in, 581, 953; (Dr. W. E. Fothergill), 863; modern, evolution of, 56; and Obstetrics, Specimens illustrating in Museum of University College Hospital, London, Descriptive Catalogue of, (Dr. H. R. Spencer and Mr. T. W. P. Lawrence) (review), 237
Gynæcology, Practical Text-book of (Dr. D. T. Gilliam) (review), 1761

H

Hadley, Mr. F. A., discussion on treatment of
Hæmatocolpos and hæmatometra, specimen of, removed from atresia vaginalis, 1689
Hæmatometra and hæmatocolpos, specimen of, removed from atresia vaginalis, 1689
fractures and their results, 730
Hæmaturia, case with attacks of, for diagnosis, 300; in cystitis, 495
Hæmin crystals, delicate method of obtaining, from minute blood-stains, 1484
Hæmo renal index (Dr. O. Grünbaum), 1339
Hæmophilia, two brothers with, 365
Hæmopericardium, traumatic, case of, operation (Dr. E. B. Gunson), 1533
Hæmoptysis, fatal case of, in baby 13 months old, 259; in early life, 321; recurring, due to small aortic aneurysm, 1355
Hæmorrhage, ante-partum, treated by Cæsarean hæmorrhage, 1133; concealed, accidental, 585; from heart, surgical emergencies in, 142; from ovary, case of, 581; internal, surgical emergencies in, 142; intracranial, surgical emergencies in, 143; cerebral, in newborn, relieved by operation, 742; severe, concealed accidental, treated by Cæsarean section, 871; from ovarian cyst, 761; some forms of, which are difficult of explanation (Dr. W. Hale White), 416; spontaneous, into kidney, 243; symptom in duodenal ulcer, 564; renal, surgical emergency in, 142; tumours to which attention is first drawn by hæmorrhage into their substance, 1144; uterine, with special reference to the abuse of the curette (Mr. B. Whitehouse), 1123
Hæmorrhagic disease in child (? scorbutic), 1536
Hæmorrhoids and chronic constipation, operation of (Dr. C. A. Bucklin), 295
Haig, Dr. A., diet and inoperable cancer, 1495
Haines, Miss G. P. H., decoration of Royal Red Cross conferred upon, 1017
Haldane, Lord, election of, to Chancellorship of Bristol University, 59
Hall, Dr. A., and Beattie, Prof. J. M., case of multiple embolic aneurysms of the pulmonary arteries, 579; diffuse neuro-fibromatosis, 579; new method of mounting museum specimens, 579
Hall, Dr. A. J., two cases of mercurial poisoning, 1467
Hall, Mr. B., medical profession and National Insurance Act, 831, 1226
Hall, Dr. D. G., case of Henoch's purpura, 169
Hall, Dr. F. de Havilland, case of abdominal tumour, 928; note on a case of mumps, 1057; use of the sphygmomanometer in general practice, opening of discussion, 1406
Hammarsten, Prof. O., Text-book of Physiological Chemistry (review), 509
Hammersmith speed-limit inquiry (Motoring Notes), 956
Hampson, Mr. W., reduction of frequency of heart-beat, 1037
Hand, right, tremor of, case of, 168
Handley, Mr. W. S., discussion on Talma-Morison operation in cure of ascites, 162
Hanging, judicial, lesion caused by, 743
Hansen, Dr. G. H. A., obituary, 545
Harcourt, Right Hon. L., M.P., speech at West African Medical Staff dinner, 250
Harford, Dr. C. F., medical profession and the National Insurance Act, 118, 256
Harman, Mr. N. B., Aids to Ophthalmology, 1912 (review), 514; new operation for squint, conjunctival reefing and advancement, 1410; some experiments to ascertain the security of sutures for squint operations, 1410
Harman, Dr. W., medical profession and National Insurance Act, 324
Harpenden Sanatorium, 1378
Harrington, Dr. C., and Richardson, Dr. M. W., Manual of Practical Hygiene for Students, Physicans, and Health Officers (review), 101
Harris, Dr. A. Butler, rôle of vaccine therapy in tuberculous joint disease in children, 21
Harris, Dr. J. D., endothelioma of the scalp, 1691
Harris, Dr. T., The Significance of Existence, 1911 (review), 733
Harris, Dr. W., alcohol injection of the Gasserian ganglion for trigeminal neuralgia, 218; and Clayton-Greene, Mr. W. H., case of congenital absence of the left half of the diaphragm simulating pneumothorax, 433
Harrison, Mr. E. F., and Self, Mr. F. A. W., estimation of nicotine in tobacco, 1555, 1644
Harrison, Dr. F. C., radium emanation in mineral waters, 1497
Harry, Dr. P. A., treatment of early stages of senile cataract, 1225
Hart, Dr. B., case of double personality, 1555
Hart, Dr. D. B., discussion on incidence of eclampsia in Edinburgh Maternity Hospital, 582; Numan of Utrecht, 168
Hartley, Mr. R. N., obituary, 1653
Hartz, Dr. W., chronic paraldehydism, 939
Harvard Medical School, new buildings at, 331
Harvey, Mr F., presentation to, 762
Harvey, Dr. W. G., clinical history and morbid anatomy of case of Addison's disease, 366; cultures and slides of actinomyces, 1132
Hassam's Arabic Self-taught (Syrian) (review), 373
Hat-pin, death caused by, 1371
Hatch, Sir E. appointment to, 337
Haughton, Mr. W. S., case of congenital dislocation of the hip treated by Lorenz's method, 583
Haultain, Dr. F. W. N., discussion on pyosalpinx, 168; discussion on transplantation of ovary, 872; discussion on maternity benefits clauses of National Insurance Act, 1539; two examples of the difficulty in diagnosis of ectopic pregnancy, 1759
Haward, Mr. W., hospitals and hospital funds, 1152
Hay, Prof. M., and daylight saving, 1025
Hay, Dr. P. J., pathology, diagnosis, and treatment of corneal ulcer, 98
Hay fever reaction outfit, 1448
Hayes, Rev. A. O., and Mackenzie, Dr. H. Gordon, Practical Hints for Pastoral Work among the Sick (review), 382
Hayes, Mr. T. R. J., X ray diagnosis of diseases of the chest, 300; of aneurysm of the thoracic aorta, 873
Hayes, Mr. T., weekly payments at St. Bartholomew's Hospital, a correction, 608
Head, Dr. H., and Holmes, Dr. G., researches into sensory disturbances from cerebral lesions, 1, 79, 144
Headache, 994
Heads, verminous, and defects of teeth in school children in Colne, 1305
Health, Biennial Conference and Exhibition on, 1213, 1295; Bill, new, for Victoria (Australia), 1795; date and place of meeting, 780; conference in Bristol, 1436; and exhibition on, at Bristol, date of meeting, 1272; exhibition and conference on, 1647; general, of China, retrospect of, in 1911, 265; of Europeans in West Africa (Dr. A. E. Horn), 1356; in Tropical and Sub tropical Countries, Some Factors Influencing (Dr. T. G. Garry) (review), 436; inspectors in San Francisco, 1027; Readings (Dr. C. J. Thomas) (review), 175; and sanitation in St. Helena, 1799; season in Egypt, 56; and Temperance Talks on (review), 1697; visitors, voluntary lectures to, 328; week, national, 896
Health of Belfast, 400; of Liverpool, 612; effect of strike (1911) upon, 1061; of Mauritius, 409; of Queensland, 402
Hearing, influence of albuminuria upon, 1650
Hearing tests, value and significance of, 795
Heart, debility of (Dr. G. A. Gibson), 1175; stages of evolution of, 1180; diastolic shock and diastolic thrill over, in case of aneurysm of first portion of aorta, 1567; dilatation of (Dr. H. Davy), 1683; (Dr. G. A. Gibson), 1175; stages of evolution of, 1180; disease of, recent advances in, 508; embryonic, growth of, after separation from body, 616; functions of, 1179; hæmorrhage from, surgical emergencies in, 142; Malformations of (Herzmissbildungen. Ein Atlas Angeborener Herzfehler in Querschnitten mit besonderer Berücksichtigung des Atrio-ventrikularsystems) (Prof. J. G. Mönckeberg) (review), 1620; measurement of energy of, 1176; observations on movements of, by means of electro-cardiograms, 866; Pathology of, Studies in Cardiac Pathology, 1911 (Dr. G. W. Norris) (review), 875; photomicrography of electrical reaction of, 132; special involvement in case of tuberculosis (Dr. P. Bahr and Dr. G. C. Low), 362; specimens from case of heart disease of rheumatic origin, 728; unusual bruit of, case of, 580; valves of, experiments on, 1179
Heart and aorta, ortho-roentgenography of, 507; and blood-vessels, therapy of diseases of, 1234; and blood pressure in pneumonia, 1667

Heart and blood-vessels, diseases of, 1788
Heart Beat, Mechanism of, with Special Reference to Clinical Pathology of (Dr. T. Lewis) (review), 731; reduction of frequency of, 1037
Heart-block, complete, with normal bundle of His, 1554; and nodal rhythm in acute infections (Dr. J. Cowan and others), 277
Heart failure, physician and pathologist on, 743, 795
Heart movements of hibernating animals, observations on, by means of electrocardiograms, 866
Heart Sounds and Murmurs, Their Causation and Recognition (Dr. E. M. Brockbank) (review), 234
Heat impulses, 3
Heath, Mr. C., new aural lamp, 932; new treatment of, for paracutic deafness, 298
Heating of schoolrooms by closed slow-combustion stoves burning coke (Dr. H. W. Sinclair and Mr. V. H. Kirkham), 1291
Heaton, Dr. G., abdominal section twice on the same patient for acute intestinal obstruction due to volvulus, 430
Heeb, Prof. W. H., Mental Discipline and Educational Values, 1912 (review), 1697
Hedonal as general anæsthetic, administered by intravenous infusion, 1568; improved apparatus for administration of, 1631; report on 75 cases (Mr. C. M. Page), 1258; infusion, anæsthesia, 794
Heels, high, evils of, 540
Heffter, Dr. A., and Ewald, Dr. C. A., Handbuch der Allgemeinen und Speziellen Arzneiverordnungslehre, 1911 (review), 996
Hehir, Lieut.-Col. P., Prevention of Disease and Inefficiency, with Special Reference to Indian Frontier Warfare, 1911 (review), 732
Heliotherapy in surgical tuberculosis, 958; in tuberculous peritonitis, 1143
Hellier, Prof. J. B., acute inversion of the uterus, 1470; Cæsarean section for labour obstructed by a suppurating ovarian dermoid cyst, 1129; vesicular mole, benign and malignant, 729
Hemiplegia, organic, finger phenomenon as new sign of, 312; in children, three cases, 365
Henderson, Dr. T. R., medical profession and the National Insurance Act, 1433
Henoch's purpura (see Purpura, Henoch's)
Henry Saxon Snell prize, 133
Henshaw's Blind Asylum, its work and financial needs, 613
Henslow, Prof. G., M. Bergson's "Creative Evolution," 456

Paton, Mr. L. J., case of holes in the macula, 505
Patton, Capt. W. S., development of the parasite of Indian kala-azar in cimex rotundatus and cimex lectularius, 743; spread of kala-azar through the instrumentality of the bed bug, 520
Paul, Mr. E. T., colitis, opening of discussion on, 435; discussion on diagnosis and treatment of gastro-duodenal ulceration, 167; on perforation in duodenal ulcer, 993
Paul, Mr. F. T., discussion on unusual breast tumour, 799
Paul, Dr. M. E., discussion on insanity with myxœdema, 822
Pauper lunatics and idiots (Parliamentary question), 1103
Paupers, classification in Wales, 398; indoor, surgical treatment of, and Bristol Guardians, 1306; sick, "classification" of, in Bristol, 1023
Payments, weekly, at St. Bartholomew's Hospital, a correction, 608
Payton, Mr. C. A., M.V.O., and Ball, Mr. E. Reynolds, Sport on the Rivieras, edited by (review), 175
Peachey, Mr. G. C., history of St. George's Hospital, 624
Peacock, Dr. S., charge against, 129, 1376; trial of, 1029
Peacocke, Dr. G., cancer of the pancreas with pancreatic cyst, 729; miliary cancer of the peritoneum, 729
Pearse, Dr. W. (the late), presentation of portrait of, to Plymouth Athenæum, 957
Pearson, Dr. C. Y., Modern Surgical Technique in its Relation to Operation and Wound Treatment, 1911 (review), 1204
Pearson, Dr. D. K., obituary, 1504
Pearson, Mr. G. H., case of meningitis in which the bacillus coli communis was obtained from the cerebro-spinal fluid, 722
Pearson, Prof. Karl, pigmy crania from Egypt, 1154
Pedrick, Mr. G., Manual of Heraldry (review), 373
Pellagra, National Conference on, date and place of meeting, 1238; new treatment of, 1638; in Nyasaland, 314
Pellagraphobia, 1421
Pelves, female, improved method of measuring internal diameters of, 872
Pelvic inflammation causing diverticulitis, 871
Pelvic outlet, contraction of treatment, 582
Pembroke township, medical officership of, 127
Penal cases decided at General Medical Council, 1625, 1627
Penfold, Dr. W. J., and Hort, Dr. E. C., the causation of toxic symptoms following the administration of salvarsan, 757, 897; salvarsan fever, 579
Pennell, Dr. T. L., death of, 1239; obituary, 961
Pennsylvania, tuberculosis in, campaign against, 396
Penny, Mr. A. F., acute inflammation of the middle ear, 233
Pentosuria, 484
Pepler, Mr. D., The Care Committee, the Child, and the Parent, 1912 (review), 1696
Pepper, Prof. W., and Austin, Dr. J. H., complete heart-block with normal bundle of His, 1554
Percival, Mr. A. S., Prescribing of Spectacles, second edition, 1912 (review), 1036
Pericarditis, purulent, case of, 927
Perineal operations, staffs for performance of, 1283
Perineum, lateral incision of, 872
Peritoneal cavity, regurgitation of blood into, from uterus in case of complete absence of vagina, 1471; surgical emergencies in, 140
Peritoneum, biochemical studies of, based upon new methods of intra-vitam staining, 1185; miliary, cancer of, 729
Peritonitis, general suppurative, cases of appendicitis with, 1255; localised, cases of appendicitis with, 1254; pneumococcal, relative value of immediate and delayed laparotomy in, 165; suppurative puerperal, abdominal section for right oöphoritis, cellulitis, slight salpingitis, 1201; tuberculous, helotherapy in, 1143; treatment of, in adults by operation, 506; treatment by abdominal drainage (Mr. C. Wallace), 1603
Perkin, Dr. W. H., and Kipping, Dr. F. S., Organic Chemistry, 1911 (review), 1620
Pernet, Dr. G., discussion on syphilis, 1687
Perrin, Prof. M., and Etienne, Prof. G., hæmolytic jaundice due to male fern, 939
Perry, Brig.-Surg., obituary, 255
Personal Calendar, a Monthly Index of Political, Official, and Social Changes, 1912 (review), 656
Personality, double case of, 1555
Personality in medical teaching (leading article), 309
Persons apparently normal, vagaries of, 214
Perspiration, tuberculous, virulence and contagiousness of, 1026
Pessary, vaginal, retained for 29 years, perforation of bladder and fixation of instrument by large phosphatic vesical calculus, lithotripsy, recovery (Mr. A. C. Butler-Smythe), 575
Pest-hole of Pacific—Guayaquil, 812
Peters, Dr. B. A. I., bed isolation of cases of infectious disease, 1225
Peterson, Prof. F., and Church, Prof. A., Nervous and Mental Diseases, 1911 (review), 1693
Pétrissage, abdominal, as aid to diagnosis of tape-worm, 1421
Petrol, danger of, in sewers, 1661
Petrol motor, dual method of exploring, 396
Pfuhl, Prof. Dr. E., Prof. Dr. G. Gaffky, und Prof. Dr. J. Schwalbe, Gesammelte Werke von R. Koch (review), 1134
Phagocytes from absorption point of view, 228
Phagocytic action of chemically treated Danysz exudates, 1737
Pharmaceutical research, some developments in, 522
Pharmaceutical Society, 1292; work of, 1485
Pharmacists, colonial and reciprocal agreements, 815; giving of copies of prescriptions by, 825
Pharmacological research, 624
Pharmacology, Experimental (Die Experimentelle Pharmakologie), second edition, 1911 (Dr. H. H. Meyer and Dr. R. Gottlieb) (review), 653; Materia Medica (Dr. W. Hale White) (review), 654; and Therapeutics, Phillips Library of, Marischal College, University of Aberdeen: Subject Catalogue (review), 373
Pharmacopœia Committee's report, General Medical Council, 1629
Pharmacy, Materia Medica (Dr. W. Hale White) (review), 654
Pharmacy Acts, administration of, 445
Pharyngeal suppuration, course and direction of various types, 780
Pharynx, epithelioma of lower end of, excision of, 431
Phenyl-hydrazine and Fehling tests for dextrose in urine, comparative sensitiveness of, 1774
Philadelphia, new dispensary building in, 1027
Philip, Dr. R. W., recognition of work of, 1790; report on Edinburgh model of defence of children against tuberculosis, given at International Congress at Rome, 1157; schools for tuberculous children, 1226

Philips, Mr. J., a few practical points in some surgical cases, 1134
Phillips, Prof. J., acute yellow atrophy of the liver in a child, 1354
Phillips, Mr. M. H., severe concealed accidental hæmorrhage treated by Cæsarean section, 871
Phillips, Dr. S., National Insurance Act and the hospitals, 755
Phillips, Mr. S., Social Work in Hospitals (review), 1698
Phillips, Dr. W. C., Diseases of the Ear, Nose, and Throat, 1911 (review), 653
Phillips, Library of Pharmacology and Therapeutics, Marischal College, University of Aberdeen, Subject Catalogue (review), 373
Phillipson, Sir G. H., appointment of, 447
Phlebitis with thrombosis, operation for, 296, 682
Phlegmonous gastritis, acute, with erysipelas, 182
Phosphates, organic, in protein food, 658
Photography in medicine, 1171
Photomicrography of electrical reaction of heart, 132
Phthalein test in relation to renal function, 1289
Phthisis, fibroid, and Workmen's Compensation Act (Parliamentary question), 1246; miners', 697; in Transvaal, 121; notification of, in Scotland, 1583; Royal Commission on, West Australia, 617; sanatoriums for, in South Africa, 401; surgical treatment of, 761; use of tuberculin in, 1540
Physical Examination (Semeiotica Fisica et Funzionale (Dr. U. Gabbi) (review), 1545
Physicians, French, prosecution of, 263
Physics, appointment of professor of, Calcutta, 1727; Manual of (Mr. H. C. H. Candy (review), 806; Practical, Notes on (Mr. A. H. Fison) (review), 806; and Chemistry, Handbook of (Mr. H. E. Corbin and Mr. A. Stewart) (review), 805
Physiology, New, in Surgical and General Practice (Dr. A. R. Short) (review), 1541; Practical, Chemical, and Physical Methods (Physiologisches Praktikum: Chemische und Physikalische Methoden) (Prof. E. Abderhalden) (review), 1692
Physiology and hygiene, teaching of, and Board of Education, 1415; Comparative (Dr. H. Winterstein) (review), 587; Elements of, especially Adapted for Nurses (Mr. W. B. Secretan) (review), 1413
Physiotherapy, Congress of, Paris, 476; Proceedings, 1094
Physostigmine salicylate, "tabloid" ophthalmic, 1786
Phytin and lecithin, pharmacology and therapeutics of (Dr. W. Brain), 918
Pic, M., and Bonnumour, M. S., Précis des Maladies des Vieillards, 1912 (review), 589
Pickerill, Dr. H. P., Prevention of Dental Caries and Oral Sepsis, 1912 (review), 1542
Pierce, Dr. B., psychiatry in England, its present state and outlook, 1017
Pigmentation (probably arsenical) of trunk, neck, and shins, case of, 232; and pruritus of skin, 25
Pill, patent, 1447
Pilocarpine nitrate, "tabloid" ophthalmic, 1786
Pineal body, tumours of, 245
Pipe, cigar, or cigarette, relative merits of, 1019
Pipette, blood-counting, new, for estimating numbers of leucocytes and blood parasites per cubic millimetre, 438
Pine, Dr. J., organisation of an anti-tuberculosis crusade, 1432
Pituitary body, disease of, without acromegaly, 1410; and glycosuria, 631
Pituitrinum and adrenalin, influence of, upon respiratory metabolism, 1788
Placenta, chorio-angioma of, 1759; and ovum, biochemical studies of, based upon new methods of intra-vitam staining, 1183; prævia, embryotomy after version for, 1340; treatment of, 800
Plague, bubonic, 366; cow-dung as preventive of, 700; diminution of, in cold weather in India, 960; investigation of, at Mukden, 1003; mortality from, in India, 186; propagation of, without aid of infected rats, 312, 322; spread of, by ingestion, 1298; (leading article), 1141; possible through agency of Panama Canal (leading article), 375; and cholera in Near East, 1234; at Basra, 1235, 1721; at Bushire, 1235, 1721; at Durban, 693, 1028; at Jeddah, 689, 1235, 1721; in Caracas, 1908-9-10 (Dr. P. F. Arreaza Colatrava) (review), 175; in Eastern Bengal and Assam, 529; in India, 402, 1098; (Parliamentary question), 841; reports on investigations into, 529; in Kirghiz Steppes, 688, 1235; in Mersina, 689; in Odessa, 688; in Punjab, statistical investigations of, 529; in Rajputana, 1239; in Russia and the Near East, 688; in Smyrna, 688; vaccines, report on investigations into, 529
Plague and cholera in Near East, 1720
Plant, Life of the (Prof. C. A. Timiriazeff) (review), 1765
Plasmon biscuits, 1283
Plender, Sir W., appointment of, as independent accountant for medical men upon question of National Insurance Act, 1791
Pleural membranes, study of pain-sense in, 109; and Lungs, Applied Anatomy of (Dr. J. C. Dickey) (review), 587
Pleurisy, including Empyema and Bronchiectatic Conditions (Dr. A. James) (review), 303
Plymouth board of guardians, 1723
Plymouth, crèche, proposed, for, 197; proposed school clinic at, 328
Plymouth Athenæum, presentation of portrait of late Dr. W. Pearse to, 957
Pneumococcus vaccine in treatment of pneumonia, two cases (Mr. G. P. Jones), 575; value of, in treatment of pneumonia, 755, 829, 896, 1299; (Dr. N. Raw), 646
Pneumonia, acute dilatation of stomach in, 522; delayed resolution in, 1668; "Friedländer," 1746; double, and purulent bronchitis produced by general infection with colon bacillus, 39; lobar, examination of sputum from 16 cases of, 1666; heart and blood pressure in, 1667; pathology and clinical history of, moot points in (Dr. P. Kidd), 1589; physical signs in, 1666; in relation to influenza, 1668; in relation to rheumatic fever, 1668; in relation to tuberculosis, 1667; respiration in, 1665; some moot points in pathology and clinical history of (Dr. P. Kidd), 1665, 1746; (leading article), 1768; sputum in, 1665; simulating intestinal perforation in convalescence from typhoid fever, 1075; termination of, in fibrosis, 1668; treated with pneumococcus vaccine, two cases (Mr. G. P. Jones), 575; by pneumococcus vaccine, 755, 829, 896, 1299; value of pneumococcus vaccine in (Dr. N. Raw), 646; and pulmonary tuberculosis, leucocytes in, 1772; streptococcal, 1740; in treatment of, 755, 829, 896, 1299
Pneumosan as remedy for tuberculosis, 897

Pneumothorax, post-operative, case treated under negative pressure, 430
Pockley, Dr. F. A., of Sydney, complimentary dinner to, 402
Poison, murder by, 883, 1020; of laburnum, 1143
Poisoning, accidental, 553; by arsenic, murder by, 1225; Cases of, Course of Action on (Dr. W. Murrell) (review), 1281; epidemic of, in Berlin, termination of, 264; industrial (Parliamentary question), 698; irritant, from chewing shoots and leaves of Dieffenbachia seguina (Dr. A. Napier), 1058; murder by, arsenic and (leading article), 1070; mysterious epidemic of, in Berlin, 63; post-anæsthetic, 1130; vindictive, of babies, 838; (also see Carbon monoxide poisoning; Chloroform poisoning; Industrial poisoning; Lead poisoning; (Meat poisoning; Ptomaine poisoning)
Poisons, organic, supposed presence of, in air, 452; schedule, 813
Police, bench, and Assistance Publique of Paris, conflict between, 1576
Polyclinic established at Nagyvárad, 1096
Poliomyelitis, acute, and allied conditions, 651; and allied conditions (Dr. E. F. Buzzard), 922; deaths from, in United States, 543; epidemiology of, 181; notification of, in Bristol, 1024; anterior, in Birmingham, 1911, 126; epidemic, clinical and epidemiological aspects of, 451; compulsory notification in County of London, 673; experimental and pathological investigations into, 451; (leading article), 516; report and papers on, 450; visceral lesions of, 244; experimental (Dr. F. E. Batten), 413; infantile, war on, in United States, 201; recent outbreak of, at Stoke Rivers, 607, 758
Polycythæmia (see Erythræmia)
Polyglandular syndromes, 1716
Polypus, benign adenomatous, of body of uterus, left salpingitis, old pyosalpinx, 1201; mucoid, of cervix, 871
Polyps, multiple, of large intestine, with toxæmic symptoms, case of, 229
Pomeroy Dispensary, Ireland, 62
Poncet, M., virulence and contagiousness of tuberculous perspiration, 1026

Territorial force, physical fitness of, 1142
Terry, Mr. H. G., four inches of stem of thermometer removed from the bladder of an old man, 232
Testicle, malignant disease of; operation for removal of ilio-lumbar lymph-glands when secondarily affected, or as precautionary measure at time of excision of organ primarily diseased (Sir H. Morris), 635; radical operation for, 534, 606; treatment by radical operation (Mr. H. M. Davies), 418
Testimony, medical (leading article), 1140, 1148
Tetanic spasms occurring in chronic ulceration of leg (Dr. M. D. Roberts), 1608
Tetanus, abortion, 1471; dangers of anti-tetanic serum therapy, 1162; Sir D. Semple's researches in, bearing of, on surgery, 682; serum treatment in, 1369
Text-books, essential information acquired from, 937
Thain, Mr. L. L., medical profession and the National Insurance Act, 53
hecal (lumbar) puncture, convenient and simple apparatus for, 104
Therapeutics, Materia Medica (Dr. J. M. Bruce and Dr. W. J. Dilling) (review), 1761; (Dr. W. Hale White) (review), 654; Medical and Surgical (Sir W. Whitla) (review), 1693; modern catalogues of manufacturing chemists, useful guides to, 409
Thermometer, clinical, new design of, 1207; four inches of stem of, removed from bladder of old man, 232
Thermos saline infusion apparatus, 1480
Thiers, M. J., and Garnier, M. M., bacteriology of the renal form of typhoid fever, 1485
Thigh, gummatous infiltration of, 168; sarcoma of, 799
Thingoe rural district, report of medical officer of health, 950
Thiocol, 307
Thiroloix, M. J., and Mora, M., febrile form of cancer of the rectum, 246
Thomas v. Barker, 124
Thomas, Dr. C. J., Health Readings, 1911 (review), 175
Thomas, Mr. J. L., discussion on exophthalmic goitre, 504
Thomas, Dr. J. R., discussion on cancer of œsophagus with perforation, 874
Thomas, Mr. W. T., diagnosis and treatment of calculi in the ureter, 727; treatment of wry neck, 649
Thompson, Dr. F., bed isolation of cases of infectious disease, 1153
Thompson, Mr. G. H., discussion on spa treatment of neuritis, 726; discussion on radium emanations of mineral waters, 1200
Thompson, Dr. H. T., and Sinclair, Dr. J., telegraphists' cramp, extract from the report of the departmental committee, General Post Office, on the subject, with additional matter, 888, 941, 1008
Thompson, Dr. T., two brothers with hæmophilia, 365
Thompson, Sir W., discussion on children's mortality from non-notifiable infectious diseases, 1341
Thompson, Prof. W. H., discussion on cerebellar tumour, 873
Thomson, Prof. Alexis, discussion on treatment of simple fractures, 797; and Miles, Mr. A., Manual of Surgery: vol. i., General Surgery, 1911 (review), 99
Thomson, Dr. D., new blood-counting pipette for estimating the numbers of leucocytes and blood parasites per cubic millimetre, 438
Thomson, Dr. F., bed isolation of cases of infectious disease, 1019, 1368; differential diagnosis of certain infectious diseases, 566
Thomson, Mr. G., Sleep and Digestion, 1912 (review), 1348
Thomson, Lieut.-Col., F. W., dinner to, 1790
Thomson, Mr. G. S., Milk and Cream Testing, 1911 (review), 372
Thomson, Prof. J. A., and Geddes, Mr. P., New Tracts for the Times: I. Problem of Sex, 1912 (review), 654
Thomson, Dr. S., intrinsic cancer of the larynx treated by laryngo-fissure, 504; operative treatment of sphenoidal sinus diseases, 1688
Thomson, Sir StClair, discussion on chronic loss of voice, 1341; elected corresponding member of Wiener Laryngologische Gesellschaft, 666
Thomson, Dr. T. L., appointment of, 1024
Thomson, Dr. W. H., Life, Death, and Immortality, 1911 (review), 514
Thoracic glands, lateral, enlarged, diagnostic value of, 379
Thoracic wounds implicating diaphragm, surgery of, 666
Thorium in treatment of leukæmia, 959
Thorium products, therapeutic action of, 1438
Thorium and radium, therapeutical applications of, 1787
Thorne, Dr. W. Bezly, discussion on use of sphygmomanometer in general practice, 1408
Thornton, Mr. G. L., case of hydatidiform mole, 298
Thorold, Brig.-Surg. H. T., death of, 1297
Thorpe, Mr. R., medical profession and the National Insurance Act, 120
Thresh, Dr. J. C., origin and wholesomeness of the saline waters in London Basin, 311, 315
Thresh, Miss M., and Christy, Mr. M., mineral waters of Essex, 521
Throat, "aching," 505; (Dr. W. H. Kelson), 642; clutching at, during suffocation, 1316; disorders of, vicious circles associated with (Dr. J. B. Hurry), 1265; Nose and Ear, diseases of (Prof. W. L. Ballenger) (review), 170; (Dr. W. C. Philips) (review), 653
Thrombosis accompanying phlebitis, operation for, 296; in phlebitis, operation for, 682; of abdominal aorta and obliterative arteritis in same case, 246; venous, of colon causing obstruction, case of, 1688
Thumb-nail, split, advice as to treatment required, 907
Thursfield, Dr. J. H., case of green teeth, subsequent to prolonged jaundice, 580; investigations into a series of post-anæsthetic deaths at the Hospital for Sick Children, Great Ormond-street, in 1907, 434
Thyroid extract, administration of, inducing glycosuria, 630; excessive use of, 751
Thyroid gland, fibro-cystic adenoma of, 929; influence of, upon carbohydrate metabolism, 630; and glycosuria, 629
Thyroid tumour at base of tongue, 433
Thyroidectomy, partial, under local anæsthesia, with special reference to exophthalmic goitre (Dr. T. P. Dunhill), 422
Thyroiditis, ligneous, case of (Dr. G. R. Murray and Mr. F. A. Southam), 1188
Tibia, osteo-periostitis of, congenital syphilitic, two cases, 1536; right, transplantation of left fibula to supply deficiency of, 1614; spine of, fracture of, or degenerative changes, question of, in case of injury to knee, 711; ununited fracture of ulna treated by bridging gap with slice sawn from, 1536
Ticks, a Monograph of the Ixodoidea (Dr. G. F. Nuttall) (review), 303
Tidy, Dr. H. L., and Panton, Dr. P. N., myeloid leukæmia, chronic and acute, 1328
Tile, glazed, virtues of, 1705
Tilley, Mr. H., discussion on intrinsic cancer of larynx treated by laryngo-fissure, 505
Tillmanns, Dr. H., Lehrbuch der speziellen Chirurgie, 1911 (review), 513
Timiriazeff, Prof. C. A., Life of the Plant, 1912 (review), 1765
Tinea, campaign against, in France, 1162
Tinne, Dr. P. F., discussion on diagnosis and treatment of gastro-duodenal ulceration, 167
Tisdale, Mr. C. W. W., Milk Testing, a Simple Practical Handbook for Milk Producers and Distributors (review), 372
Tissues, Diseased, Methods of Preserving and Examining, in Post-mortem Examinations (Dr. F. Delafield and Dr. T. M. Prudden) (review), 652; life of, outside the organism, 263
Titanic, late surgeon of, 1376, 1437; the, disaster to, 1071; loss of medical officers of, 1307; wreck of, 1502
"Toaster," useful, 479
Titles, medico-military, in India, 1727
Tobacco, consumption of, in France during 1910, 1650; nicotine in, 945, 1555, 1644; toxic factor in, 944, 1511
Tobacco smoke, alkalinity of, 946; nicotine in, 946
Tobin, Mr. R. F., appointment of, 1725
Todd, Dr. C., decoration conferred upon, 247
Todd, Dr. J. L., and Wolbach, Dr. S. B., diagnosis of sleeping-sickness by gland palpation and puncture, 1423
Toe, ulceration of, in case of hydrocephalus, 929
Tombleson, Dr. J. B., psychotherapy and general medicine, 390
Tongue, epithelioma of, case of, 165; thyroid tumour at base of, 433; depressors, envelope for, 658
Tonic spasm of muscles, chiefly of extremities (? myotonia), 1536
Tonsillar region, right swelling in, 433
Tonsils, enucleation of guillotine for, 1206; and appendix, functions of (Mr. K. H. Digby), 160; removal of, 1773
Tooth-plate, impacted œsophagotomy for, 1273
Toronto, division of professional fees in, 330; new hospital journal for, 762
Torquay, health of, 1166; medical baths at, 205
Torquay Isolation Hospital, action for negligence against, upheld, 957
Torrens, Dr. J. A., case of unusual cardiac bruit, 580
Tourniquet, improved, 1349
Town planning in India, 1727; and housing in Canada, 195
Town Planning Bill, South Africa, 66
Townsend, Mr. C. F., The Washhouse and All About It, 1911 (review), 372
Toxæmia (see Chloroform toxæmia)
Toxic drugs, sale of, in France, 1438
Toxic eruptions, drug eruptions in relationship to, 972; of skin, 969
Toxic factor in tobacco, 944, 1511
Toxic origin of eruptions other than erythemas and urticarias, 972
Toxic symptoms following administration of salvarsan, causation and prevention of, 757, 828, 897
Toxicity following administration of salvarsan, causation and prevention of (Dr. J. McIntosh and others), 637
Toxicology and Chemistry, Medical Text-books of (Dr. J. W. Holland) (review), 1620
Toxicology, Manual of (Dr. R. A. Witthaus) (review), 102
Toxins and Microbes (Dr. E. Burnet) (review), 1543
Toxins in dermatology, origin and development of idea of, 969; of bacterial origin, absorbed from some distant focus of infection, 973; which give rise to erythematous and urticarial eruptions of skin, 969
Trachoma bodies, 381
Trade and medical practice, legal distinction between, 1294
Trade in patent and proprietary medicines, Select Committee on (leading article), 1284
Training for rowing, 954
Tramps of Sussex, 1249
Transactions of the American Surgical Association, vol. xxviii. (review), 1206
Transfusion of blood, indications for, 1650
Transmutation of Salmonella group of organisms, experiments on, 706
Transplantation, Heteroplastic and Homoplastic (Dr. G. Schöne) (review), 1543
Transport in France and tuberculosis, 1237
Transvaal, miners' phthisis in, 121
Trask, Assistant Surg.-Gen. J. W., A Digest of the Laws and Regulations of the Various States Relating to the Reporting of Cases of Sickness, 1911, (review), 878
Trauma as cause of appendicitis, references to literature required, 71; as factor in disease, 230; as factor in some diseases of nervous system, 509
Traumatic parthogenesis, 1391
Treasury of Human Inheritance, Dwarfism (Dr. H. Rischbieth and Miss Amy Barrington) (review), 1474
Treatment, Dictionary of, including Medical and Surgical Therapeutics (Sir W. Whitla) (review), 1693; Index of, by Various Writers, 1911 (review), 803; Practical, Handbook of, 1911 (review), 26

END OF THE FIRST VOLUME FOR 1912.

PRINTED and PUBLISHED by the PROPRIETORS, WAKLEY AND SON (1912), LTD., at No. 423, Strand, and Nos. 1 and 2, Bedford-street, Strand, in the Parish of St. Martin-in-the-Fields, Westminster, in the County of London.—Saturday, July 6th, 1912.

Researches
INTO
SENSORY DISTURBANCES FROM CEREBRAL LESIONS.[1]

BY HENRY HEAD, M.D. CANTAB., F.R.S.,
PHYSICIAN TO THE LONDON HOSPITAL;
AND
GORDON HOLMES, M.D. DUB.,
ASSISTANT PHYSICIAN TO THE NATIONAL HOSPITAL, QUEEN-SQUARE, AND TO THE SEAMEN'S HOSPITAL, GREENWICH.

INTRODUCTORY REMARKS.

WE must begin by craving the indulgence of our readers for the form in which the following paper is cast. The nature of the sensory changes produced by lesions of the cerebral cortex and other parts of the brain has been the theme of innumerable works by the acutest intellects in medicine of the last 50 years. Our research would have been impossible but for their labours, and yet we can never acknowledge what we owe to them. Many whose views have helped to make our work fruitful are known to us through their publications, and to them we can repay our debt by referring at suitable points to the similarity of our results to those of our predecessors. Others have been our teachers and the masters for whom we have gladly worked. To them our debt can never be repaid, for much of the identity in outlook comes from personal intercourse and cannot be fixed by citation. First amongst this group must always stand the name of Dr. Hughlings Jackson.

Scope of Communication.

This paper is a preliminary communication in which we put forward a general view of the mode of action on the afferent side of the nervous system. Any such generalisation must not only contain much that is common to the views of others, but also many things incompatible with the conceptions even of those with whom we are otherwise in harmony. Where possible we shall always acknowledge our concurrence with those who have preceded us, but in the small space at our disposal we cannot enter into criticism of work with which we are not in agreement. In many cases, although our theoretical conclusions may coincide with those put forward by other workers, our experimental results may differ fundamentally. In the same way similar clinical observations may lead us to other conclusions, but it will be impossible to stop our exposition in order to discuss these differences.

We shall attempt to put forward in this paper a general conception of the mechanism underlying sensation based upon a study of human beings in whom disease, accident, or surgical interference has produced some stationary lesion. Many of these patients have occupied our attention from time to time for many years, and it will be impossible in this preliminary communication to give a complete history of all our cases.

Methods of Investigation.

We lay great stress upon the methods we have used for testing sensibility in this research. As these, however, have only limited interest we shall publish them elsewhere. As far as possible we shall avoid the use of all general terms. We wish to lay peculiar stress on the confusion which arises from the use of all such expressions as "deep sensibility" when reporting the results of a clinical examination. Not infrequently "deep sensibility" is said to be affected from a lesion of the cortex when the observer means to state that the appreciation of posture, of passive movement, or of vibration, was defective. Similarly, "atopognosis" is a combined loss of the faculties of recognising posture and the situation of the spot stimulated, two functions capable of independent investigation. In every case, therefore, we shall describe our observations under headings which imply the simple test used in analysing the loss of sensation.

We shall begin by tracing sensory impulses from the point where they enter the spinal cord and follow them to those centres where they form the basis of that psychical process we call sensation. For this investigation exact knowledge of the site of the lesion is less important than a precise determination of the nature of the sensory changes in selected cases. It is only by the study of the nature and grouping of these affections of sensation that we can obtain any knowledge of the nature of cerebral activity and of the form in which impulses reach the higher centres to underlie the psychical elaboration of sensation.

Nature of Lesions.

It is our pleasant duty to express our sincere thanks to all those who have helped us in this work. To the staff of the National Hospital, Queen-square, we owe innumerable opportunities of observing many valuable cases, and Dr. Head wishes to thank them for their generous hospitality. To Sir Victor Horsley we are particularly grateful for permission to use our observations on his remarkable case of excision of a portion of the cerebral cortex.

In consequence of such help we have been able to investigate a large number of selected cases. This includes patients in whom the clinical symptoms justified us in assuming certain affections of the optic thalamus. A second group consists of patients with limited lesions of the surface of the brain, most of which resulted from successful removal of a cerebral tumour or other cortical disease. In this group the site of the lesion is known with more or less accuracy, and we have included solely stationary cases examined months or years after operation. Finally, we have employed the same methods to investigate many instances of lesions in the neighbourhood of the internal capsule and deeper parts of the brain.

I.—THE GROUPING OF AFFERENT IMPULSES IN THE SPINAL CORD AND BRAIN-STEM.

1. THE SPINAL CORD.

It is a matter of universal belief that man has been evolved from the lower animals; and yet when we deal with sensation and sensory processes we speak as if he were created with peripheral end-organs, each capable of reacting to one of the sensory qualities of human experience. The impulses starting in these end-organs are supposed to pass unaltered to the brain, there to set up that peculiar and unknown change which evolves a specific sensation. Spots were found on the skin sensitive to touch, to pain, to heat or to cold only. With the discovery of these highly developed end-organs the doctrine of specific nerve energy seemed to be proved in the strictest manner.

All other forms of sensory appreciation were supposed to be produced by the physical transformation of these primary sensory elements, in association with an ill-defined faculty called the "muscle-sense." Recognition of the locality of a stimulus and the posture of the limb under examination were attributed to judgment and association.

But alongside the systematic investigation by von Frey and others of the capabilities of these specific areas in the skin, the clinicians were discovering the importance of "muscular sensibility." Sherrington's demonstration of afferent fibres in muscles and tendons placed the existence of the "muscle-sense" beyond a doubt. The use he made of these afferent impulses from deep structures in his theory of the proprioceptive system necessitated a complete exploration of the nature of deep sensibility.

By their experiment directed to this end, Rivers and Head [31*] showed that beneath the skin, independent of all "touch" and "pain spots," lies an afferent system capable of a wide range of functions. Pressure that in ordinary life would be called a touch can be appreciated and localised with considerable accuracy. Increase of pressure, especially on bones and tendons, will cause pain. Moreover, it is from the impulses of this deep afferent system that we gain our knowledge of the posture of the limbs and the power of recognising passive movements.

Complexity of Peripheral Mechanism of Sensation.

Evidently, therefore, the peripheral mechanism of sensation is less simple than was at first supposed. For there are two sets of end-organs that can respond to tactile stimuli and

[1] The substance of this paper formed the Croonian lectures delivered before the Royal College of Physicians of London on June 13th, 15th, 20th, and 27th, 1911. The results will be published in more detail in the forthcoming number of *Brain*.

* These and other reference numbers relate to a bibliography to appear at the end.

two independent mechanisms for the initiation of pain. Further analysis showed that the peripheral apparatus in the skin, by which we become conscious of the nature of external stimuli, is highly complex. No one sensory quality is subserved by a single set of end-organs, but every specific sensation is the result of the combined action of more than one group. This is exactly the result that might have been expected when we bear in mind that the structure of man is the product of a long evolution.

Grouping of Different Impulses in Spinal Cord.

But it is equally obvious, from an evolutionary standpoint, that these diverse impulses could not pass uncombined to the highest physiological level. Within the spinal cord the opportunist grouping of the periphery gives place to an arrangement according to quality (Head and Thompson [11]). All impulses capable of generating pain become grouped together in the same path and can be disturbed simultaneously by an appropriate lesion of the spinal cord. In the same way sensibility to heat or to cold may be lost independently of one another, showing that all the impulses upon which they are based have been sorted out into two functional groups, each of which passes by a separate system in the spinal cord.

The most remarkable condition revealed by an intramedullary lesion is the complete separation of the impulses underlying the appreciation of posture, the discrimination of two points and their correlated faculties from those of other sensory groups. All tactile, painful, and thermal impulses coming from the periphery undergo regrouping after entering the spinal cord, and whether they arise in the skin or in deeper structures become arranged according to functional similarity. Then, after a longer or shorter course, they pass away to the opposite side of the spinal cord.

Impulses concerned with Postural and Spacial Recognition.

This process of filtration leaves all the impulses concerned with postural and spacial recognition to continue their course unaltered in the posterior columns; they are the survivors of peripheral groups dissociated by the passing away of certain components into secondary afferent systems. At any point in the spinal cord these columns transmit not only impulses from the periphery which are on their way, after a longer or shorter passage, to regrouping and transformation, but at the same time they form the path for impulses, arising both in the cutaneous and deep afferent systems, which undergo no regrouping until they reach the nuclei of the medulla oblongata.

Thus a lesion confined to one half of the spinal cord, even at its highest segment, may interfere with the passage of sensory impulses, some of which are travelling in secondary paths, whilst others are still within the primary level of the nervous system. All impulses concerned with painful and thermal sensations from distant parts, disturbed by such a lesion, will be travelling in secondary paths, and will have come from the opposite half of the body, for after regrouping they have passed across the spinal cord. But those impulses underlying the appreciation of posture, the compass-test, size, shape, form, weight, consistence, and vibration will be affected on the same half of the body as the lesion. They still remain in paths of the peripheral level and have undergone no regrouping.

In such a case the parts on the side opposed to the lesion may be insensitive to pain, heat, and cold; but all the postural and spacial aspects of sensation will be perfectly maintained. Yet all power of recognising position, of estimating size, shape, form, and weight, or of discriminating the two compass points will be lost in the limbs which lie on the side of the lesion, although tactile sensibility and localisation of the spot stimulated may be perfectly preserved.

This remarkable arrangement enables us to analyse the nature of the peripheral impulses upon which depends our power of postural and spacial recognition. Obviously, even at the periphery, they must be independent of touch and pressure. The power to distinguish two points applied simultaneously and to recognise size and shape requires as a preliminary the existence of sensations of touch. But the patient may be deprived of all such powers of spacial recognition without any discoverable loss of tactile sensibility. In the same way our power to appreciate the position of a limb, or to estimate the weight of an object, is based upon impulses which, even at the periphery, exist apart from those of touch and pressure called into simultaneous being by the same external stimulus.

This long delay of the postural and spacial elements in reaching secondary paths enables them to give off afferent impulses into the spinal and cerebellar coördinating mechanisms which lie in the same half of the spinal cord. The impulses which pass away in this direction are never destined to enter consciousness directly. They influence coördination, unconscious posture and muscular tone, and although arising from the same afferent end-organs they never become the basis of a sensation.

Finally, the last survivors of these impulses from the periphery become regrouped in the nuclei of the posterior columns and cross to the opposite half of the medulla oblongata in paths of the secondary level. So they pass to the optic thalamus and thence to the cortex to underlie those sensations upon which are based the recognition of posture and spacial discrimination.

Illustrative Case.

The following case is an example of the effects produced by a lesion situated in one-half of the spinal cord just below the point at which the postural and spacial impulses become regrouped in the nuclei of the posterior columns.

CASE 1. *Brown-Séquard paralysis.—On the right*—Weakness of arm and leg. Reflexes exaggerated; ankle clonus and extensor plantar reflex. Loss of painful sensibility over right cheek: touch, heat, and cold unaffected. *On the body and limbs*—Tactile, painful and thermal sensibility were perfect; but in the arm and leg posture, passive movements, and vibration of a tuning-fork could not be appreciated within normal limits, the compass test was defective, and he could not recognise size, shape, form, weight, or consistence of objects by the right hand. Localisation was not affected. *On the left*—Motion perfect. Reflexes normal. Loss of sensation to pain, heat, and cold. All other forms of sensibility, including localisation, perfectly preserved.

This case is an excellent illustration of the principles laid down in this section, and the retention of muscular power in the right hand enabled us to test the faculty of recognising size, shape, form, weight and consistence with an accuracy otherwise impossible.

Three Main Divisions of Afferent Impulses.

In conclusion we believe that at the extreme upper end of the spinal cord, just below the formation of the posterior column nuclei, afferent impulses pass upwards in three main divisions:—

1. The impulses underlying sensations of pain, of heat, and of cold are travelling in secondary paths in the opposite half of the spinal cord from that by which they entered.

2. Those impulses upon which depend postural recognition and spacial discrimination still remain uncrossed in the posterior column. They consist of one group arising in the deep afferent system, upon which depends our recognition of posture, passive movement, weight, consistence, and vibration. A second group arises in the end-organs of the skin, and these impulses underlie the discrimination of two points applied simultaneously, and the allied appreciation of size, shape, and form.

3. Contact sensibility evoked by touch and by pressure may remain entirely undisturbed. Apparently it depends upon impulses which run in a bilateral path, and it is therefore unaffected by a purely unilateral lesion (Rothmann [32], Petrén [23], Head and Thompson [11]). This tactile group formed by the union of tactile impulses within the cord carries with it the impulses which underlie the power of recognising with accuracy the situation of the stimulated spot, and localisation therefore remains unaffected.

2. THE BRAIN-STEM.

The larger number of afferent impulses traverse the spinal cord, grouped, according to their sensory qualities, in paths that can be isolated by disease. This enables us to analyse the nature of the groups formed, either by specific selection at the first synaptic junction, or by gradual filtration away into secondary tracts, of impulses arising originally in the same peripheral system. But in their further passage through the brain-stem to the optic thalamus the impulses run in paths which are anatomically more closely associated. This makes any analysis of the grouping of afferent impulses in this region unusually difficult.

Pain, Heat, and Cold Impulses.

Impulses underlying sensations of pain, heat, and cold alone seem to run unaltered between the upper end of the spinal cord and the optic thalamus.[2] They receive the accession of the regrouped secondary impulses from the face, which cross to join the specific path for pain, for heat, or for cold. These paths are so situated that they can be interrupted without disturbance of any other form of sensation on the body, and the analgesia and thermo-anæsthesia so produced resemble in quality the loss to pain, heat, and cold caused by a lesion of the spinal cord.

Thus when a lesion of the bulb interferes with sensations of pain, not only may the skin be insensitive to prick but the readings of the pressure algometer may be raised on the analgesic side. In the same way the affected area on the body may be insensitive to all degrees of heat and to all stimuli capable of evoking normally a sensation of cold. It is, however, important to remember that although the uncomfortable sensation produced by excessive pressure is greatly diminished, a lesion in this situation does not usually abolish completely all painful pressure (Cases 2 and 3). Thus it would seem that the grosser forms of pain and discomfort may possibly find their way by another path if the usual one is closed; whereas an equivalent lesion in the spinal cord blocks all painful impulses whatever their origin.

Not only can these three forms of sensibility be affected together, but any one of them may escape or be affected alone. The following case shows that, with a one-sided lesion of the bulb, the opposite half of the body may become analgesic, and yet the threshold values of sensibility to heat and cold may be equal on the two sides.

CASE 2.—October, 1906 sudden onset of pain in the right lower jaw. Since June, 1907, he has noticed loss of sensation on the left half of the body and right half of the face. First seen by us June, 1909, and since then his condition has not changed materially. Motor power and reflexes unaffected. Diplopia in all directions. Pupils unaffected. Optic neuritis in both eyes. Hearing diminished in right ear.

Sensation on the face.—Loss to prick with no loss to pressure-pain on the right side of the face, head, and neck. No other change in sensation to measured stimuli, but touch seemed "less vivid," heat "hotter," and cold "less cold," over the right than the left half of the face.

Sensation on the body.—The left half, except the perineum and scrotum, was insensible to prick. Pressure-pain was also diminished. Otherwise sensation was unaffected.

This case showed (1) a local lesion affecting the sensation of the right half of the face and neck; (2) a remote disturbance of sensibility to pain over the left half of the body with considerable raising of the algometer readings over the analgesic area; (3) heat and cold showed the same threshold on the two halves of the body.

All recent work has shown that the paths for the transmission of the impulses for pain, heat, and cold run up in the neighbourhood of the nucleus of the trigeminal nerve. This close local association is particularly well shown by cases of occlusion of the posterior inferior cerebellar artery (Wallenberg [38], Bruer and Marburg [2], Spiller [37]).

Separation of Spacial Discrimination and Postural Recognition Impulses.

In addition to these well-known facts the following instance of this condition also shows that impulses underlying the appreciation of posture and passive movement have become separated from those concerned with spacial discrimination. The compass-test gave identical results on the two halves of the body, and size, shape, and form could be appreciated on both hands. And yet the amount of passive movement necessary to evoke a sensation was three to four times greater in the affected fingers. Evidently a change in grouping has taken place at the posterior column nuclei and the impulses for spacial discrimination now tend to run apart from those of postural recognition.

CASE 3.—An instance of "occlusion of the posterior inferior cerebellar artery." Sudden onset Dec. 25th, 1908. Seen by us first in July, 1909. Horizontal and rotatory nystagmus, but diplopia had passed off. Left pupil did not dilate fully to shade. Left palpebral fissure smaller than right. Movement of left half of the palate defective, but vocal cords and tongue moved well. Gait unsteady; he tended to deviate to the left but fell to the right when his eyes were closed. No paralysis. Reflexes normal.

Sensations on the face.—Left half insensitive to prick, but sensitive to pressure-pain. Tactile and thermal thresholds were equal and normal on the two halves of the face, but all temperatures seemed "duller" on the left half.

Sensation on the body.—Loss to prick, to heat, and to cold over the right half of the body, right arm, and right leg. Sensibility to pressure-pain diminished over this area but not lost.

Diminished power of recognising posture and pressure movement in right arm and right leg. All other forms of sensation normal.

This typical case of "occlusion of the posterior inferior cerebellar artery" showed:—

1. A sensory disturbance over the left half of the face representing the local lesion.
2. Analgesia, with raising of the algometer readings, and complete loss of sensation to heat and to cold over the right half of the body.
3. Diminished recognition of posture and passive movement in the right arm and leg, but all spacial discrimination was perfect (compass-test, appreciation of size, shape, form)
4. Slight cerebellar incoördination in the left arm and leg, which was not increased by closing the eyes.

Gathering Together of Sensory Paths.

When all afferent impulses from the face have undergone re-grouping and passed, in secondary tracts, to the opposite half of the nervous system, the various sensory paths are gathered closely together in preparation for their ending in the optic thalamus. Every sensory path now lies within the opposite half to that by which its impulses entered the central nervous system. The complete integrity of sensations on the same side as the lesion shows that no bilateral paths are open to any form of sensory impulse.

From the analytical aspect these brain-stem lesions can give little information as to the grouping of the elements underlying sensation. But occasionally by watching the gradual disappearance of one form after another a hint may be gained with regard to the independence or association of any two groups of impulses.

Moreover, the tendency we have already noticed for the grosser forms of pain or discomfort to find a way to consciousness, although the more specific forms of pain, heat, or cold are blocked, becomes more evident the closer the lesion lies to the optic thalamus. And yet it is probable that this discomfort is not conducted by a bilateral path.

The following case, which we owe to the kindness of the late Dr. Beevor, illustrates the concentration of paths just before their entry into the optic thalamus. Incidentally it seems to show that the power of localising the spot touched may be greatly affected at this level with but little loss of tactile sensibility.

CASE 4.—Tumour of the right side of the mid-brain and optic thalamus verified by post-mortem examination. Five months before death the following signs were present. Loss of power in the left arm and leg, with profound ataxy. Extensor response from left sole with normal response from right. Athetoid movements of left hand, together with a fine tremor when the left arm was extended. Eye movements greatly restricted; nystagmus in all directions; fixed pupils.

The loss of sensation was confined to the left of the middle line. Sensations of prick diminished over left arm and leg, but lost on the left palm only. Tactile sensibility very little, if at all, affected during the time he was under observation by us. Localisation lost over left upper extremity. Compass-test gravely affected over left arm and leg. Appreciation of size and weight abolished in left hand.

This is a case where a malignant growth affected the corpora quadrigemina and that portion of the mid-brain at a point where the paths for sensory impulses are converging to an end in the thalamus. The clinical signs indicate that this lesion started in the mid-brain, although at the time of death the right optic thalamus was also destroyed.

During the course of the disease this case showed that:—In this situation the impulses underlying postural

[2] This does not necessarily mean that the impulses are carried by uninterrupted fibres. It has been suggested by Long [18], Cajal [4], Kohnstamm [15] that the nuclei of the formatio reticularis are intercalated in the course of the afferent conduction tracts. Such anatomical relay would not interfere with the above physiological conclusions, as it does not necessarily imply any regrouping of sensory impulses

recognition, spacial discrimination, and localisation (spot-finding) may be dissociated from those concerned with touch and pain. At one stage of his illness the patient was therefore able to appreciate contact with von Frey's hairs and cotton-wool, but could not localise the spot touched. Nor could he tell the head from the point of a pin, or the relative size and weight of objects placed in his hand.

Brain-stem: Summary.

To sum up the conclusions of this section, we can say that he brain-stem between the nuclei of the posterior columns and the final termination of all sensory paths in the optic thalamus is the seat of the following changes:—

1. The impulses for pain, heat, and cold continue to run up in separate secondary paths on the opposite side of the nervous system to that by which they entered. They receive accessions from the regrouped afferent nerves of the head and upper part of the neck. Although these paths are frequently affected together they are independent of one another, and any one of the three qualities of sensation may be dissociated by disease.

2. Lesions of the spinal cord tend to diminish simultaneously all forms of painful sensibility, but with disease of the brain-stem the gross forms of pain and discomfort may pass to consciousness, although the skin is analgesic. This applies not only to painful pressure but to the discomfort produced by excessive heat.

3. The impulses concerned with postural recognition part company with those for spacial discrimination at the posterior column nuclei. Up to this point they have travelled together in the same column of the spinal cord, but as soon as they reach their first synaptic junction they separate. Above the point where they enter secondary paths the power of recognising position and passive movement can be affected independently of the discrimination of two points and the appreciation of size, shape, and form.

4. It would seem as if those elements which underlie the power of localising the spot touched or pricked become separated off from their associated tactile impulses before they have actually come to an end in the optic thalamus. The long connexion of localisation with the integrity of tactile sensibility is here broken for the first time.

All these changes are preparatory to the great re-grouping which takes place in the optic thalamus, and will form the subject of the following section.

(*To be continued.*)

An Address
ON
INDICATIONS FOR SURGICAL INTERFERENCE IN THE TREATMENT OF TUBERCULOUS JOINT DISEASE IN CHILDREN,
WITH REMARKS AS TO THE AFTER-RESULTS.

Delivered in Opening a Discussion in the Section for Diseases of Children, Royal Society of Medicine, on Dec. 15th, 1911,

BY A. H. TUBBY, M.S. LOND., F.R.C.S. ENG.,
SURGEON (AND IN CHARGE OF ORTHOPÆDIC DEPARTMENT), WESTMINSTER HOSPITAL; SURGEON, ROYAL NATIONAL ORTHOPÆDIC HOSPITAL, ETC.

MR. PRESIDENT AND GENTLEMEN,—The terms of the reference are sufficiently vague to allow me to speak of the surgical treatment of tuberculous joint disease in children somewhat widely, but the time allotted compels me to be brief.

INTRODUCTORY REMARKS.

The discussion to-day has special reference to the indications for surgical interference, and the nature of the operation done. I have been asked to include in my remarks some notes on the treatment of abscesses; and, finally, the after-results will be touched upon. It has been agreed that the various forms of tuberculous spinal disease and its complications render the ground too wide to be traversed, and therefore they are excluded.

You will observe that, as befits this section of the Royal Society of Medicine, we are dealing with the disease in children. It appears to me, however, expedient to extend that age in this case to the end of the fifteenth year, as it may be said to mark the end of the very active period of growth in bone; and, certainly up to this time that structure retains the characteristics of early life and its reaction to tuberculous infection. It is to be hoped that speakers will not limit themselves to hospital and the poorer class of patients, but that they will also deal with well-to-do patients, although it is generally recognised that for the latter class operative interference is less frequently required. Time will not permit me to allude to the treatment of deformities arising from tuberculous arthritis, except in so far as they may necessitate operation.

In order to make the views quite clear which I entertain with regard to tuberculosis in childhood, I may state that in a general sense I am in entire agreement with the opinion of Augustus Wilson,[1] who has stated "that tuberculosis of joints can be considered as such only in its incipiency, and that all conditions following this are to be looked upon as avoidable sequelæ." This axiom involves the postulates that early recognition of the affection and proper treatment, followed by careful and long-continued observation, are essential to the thorough and radical cure of the disease without deformity and with the minimum loss of function.

Looking back upon my opportunities for clinical experience from 1882 onwards—experience which has been gained in the wards of two general hospitals, at the Evelina Hospital for Children, at the Royal National Orthopædic Hospital, and at the Hospital for Hip Disease, Sevenoaks—I am conscious that the conception of tuberculous arthritis has been undergoing during the last decade a radical change. Briefly put, we may say that, whereas formerly the affection was regarded simply as a joint-disease to be treated as such, we now look upon it as a loss of resistance to the invasion of tuberculosis into a patient, manifesting itself an an inflammation and degeneration of one or more joints; or, to put it more baldly, the earlier idea was—the joint first and the general condition afterwards, whilst the present conception is that of the general condition of the patient first and the joint secondly.

In adults this is true to a certain extent, but in children this remark is more apposite. If we contrast the reactions of adults and children to tuberculous bone affections we observe that the natural processes do not wall off the disease with such frequency as in adults. Painter[2] remarks: "This is apparently antagonistic to the fact that tubercle tends to become arrested more often spontaneously in children than in adults." In children, when an operation is performed, the highly vascular and cellular spaces are opened up with knife and chisel, and dissemination of infection into new and unguarded localities takes place. In fact, whilst in adults the healing of tubercle is accompanied by the formation of a barrier of dense fibrous tissue, in children the young and rapidly-growing tissues do not assume this sclerotic action. We may take it then that in children the general resistance to this disease is greater than the local warding-off power, and in adults the reverse is the case.

In addition to these pathological observations, the truth of which it is difficult to deny, there are certain factors which are responsible for the change in surgical opinion during the last decade. These factors are four in number—namely: 1. The climatic treatment of bone and joint tuberculosis. 2. The employment of Roentgen rays. 3. The improved use of the new tuberculins, and the evolution of methods designed to check and control their action. 4. The recognition of the value of supporting appliances, their wider use, and the ingenuity which has been displayed in inventing new apparatus or modifying old ones to meet various conditions of deformity or limitations of movement.

CLIMATIC TREATMENT.

1. Tuberculosis of joints should be treated by open-air methods exactly as pulmonary tubercle is, and results are obtained which are very gratifying. In the year 1902, at the suggestion of Dr. Dawson Williams, I collected statistics from some of the children's hospitals in London and embodied the results of the observations in my articles.[3] I

Practitioner, September, 1903. Also Tuberculous Cripples, in Kelynack's Tuberculosis in Infancy and Childhood, p. 188, London, 1907, Baillière and Co.; and Tuberculous Bone and Joint Disease in Childhood, its Effects on the Duration and Usefulness of Life, British Journal of Tuberculosis, July, 1907.

venture to think that these articles were instrumental in inducing the trustees of the Treloar Hospital at Alton to alter their original conception of the objects of their institution, and to admit for treatment tuberculous in preference to other kinds of cripples.

The articles which I wrote showed, first, that children with tuberculous joint disease are not fit subjects for systematic treatment in the wards of hospitals in towns and cities; and, secondly, that when treated conservatively in the country the number of operations required was much diminished, the severity of the operations was decreased, and the results were more satisfactory, in so far that more cures were obtained and the cures were more permanent.

Since these dates a great mass of material has come to hand bearing out fully the conclusions of the writer and enforcing these lessons. My opinion is strengthened by the results obtained at the Treloar Hospital and College at Alton and at the Sevenoaks Hip Hospital. Of the former institution Mr. H. J. Gauvain is the resident medical officer, and I am indebted to him for the following statements: "The great majority of patients, taken early, are discharged with good movement. The wage-earning capacity of patients is, I believe, little, if at all, impaired in early cases, provided that judicious employment is chosen for the patient."

I asked Mr. Gauvain to inform me as to the causes of death. He says: "You may be interested to hear that out of 336 cases, which have been under treatment here so far, only one death has occurred, and this case was that of a boy suffering from hip disease who developed tuberculous meningitis eight days after admission. You ask me whether I have been compelled to operate. In only one case have I operated—for a caseous abscess of the hip. ..... As for my opinion on the value of operative interference in the cases which have come under my notice, the results have so commonly been bad that it has made me very averse to operative interference in these joints."

THE EMPLOYMENT OF X RAYS.

2. We now pass on to the use of Roentgen rays. In diagnosis they are invaluable, but the photographs must be of the best possible type and so clearly focussed that all the details of the structure of bone are quite distinct. By their help we can see the beginning of the disease; we can watch its progress; we note the effects of our treatment and check and regulate our methods; and, I may add that in some resistant forms of tuberculous synovitis systematic exposure to the X rays has appeared to have some effect in producing retrogression of the disease.

In all cases I employ now the X rays systematically for the diagnosis of the disease and regulation of the treatment. As one proof of their practical value I may say that I have been astonished to find how frequently tuberculous disease is situated in the acetabulum as well as in the head of the femur. In fact, primary or associated acetabular disease exists much more frequently than is suspected.

3. As to the use of *tuberculins*, we are happy in being able to hear the opinion of Dr. A. Butler Harris on this point.

4. By the ingenuity of surgeons, who have given special attention to the subject, patients have been enabled to get up much earlier and to be treated by what may be called the ambulatory method, with all its advantages to general health, without running the risk of lighting up the disease or incurring a severe and disabling deformity.

ADVOCACY OF CONSERVATIVE TREATMENT.

It appears that I scarcely need evoke the opinion of my hearers on the treatment of very early and uncomplicated tuberculous arthritis. At any rate, the majority will agree that rest, protection of the joint, prevention of deformity, and treatment of the sanatorium type are indicated.

Tuberculous arthritis is a disease varying very much in intensity. In one case the affection is virulent and the course of the disease is acute, resulting, on the one hand, in rapid degeneration of the joint, with extension to the shaft and the development of osteomyelitis in the cancellous tissue, and on the other hand in rapid and destructive changes in the joint. In other cases the disease is comparatively mild and runs its course without any complications such as abscess, tuberculous diaphysitis, or the formation of sinuses, and the part recovers with little or no loss of function. In the early stages of the disease there is no possibility of telling which type exists, and unless we watch the progress of the disease constantly, by using the Roentgen rays and by clinical observation, and note the reaction of the patient to vaccination, we are quite unable to form an opinion as to its future course.

Some cases of tuberculosis are obstinate and refractory, due not so much to the local conditions as to what, for want of a better term, is called "loss of resistance" on the part of the patient. It is in those cases that the question arises, "Shall we interfere surgically or not?" when the improved general methods which I have indicated seem to have failed.

I say advisedly "seem to have failed," because the treatment of this affection is in any case a long business. It is often months before the inflammatory and destructive conditions subside and healing sets in, and it is usually two or three years before a joint can be regarded as functionally cured, whether it is mobile, ankylosed, or partly sound at the end of that time. So that my inclination is to persist and to persevere with climatic and conservative measures rather than to allow my hand to be forced to interfere surgically. We have, however, under the present conditions in this country, to weigh carefully the patient's opportunity of climatic and sanatorium treatment. Unfortunately, it may be said with truth, and I trust without offence, that the successful therapeusis, not only of pulmonary, but also of articular tuberculosis is largely a question of means and opportunity. Sufferers with ample resources stand a better chance of recovery and useful joints than impoverished hospital patients.

Nevertheless, it is my deliberate opinion that in children under 15 years of age—and to a less extent in adults, where other factors, such as the wage-earning capacity and the inability to obtain sufficient rest must be weighed—the less the extent to which surgical intervention is practised the better is the prospect of recovery of the affected part, of its regaining its functions, and of usefulness in life.

It may be urged that many lesions which have become quiescent in childhood light up in adult life. No doubt this is so, but we must consider two points—namely, that several years of freedom from the disease have been gained and the part has been useful during that time; also, that tuberculous arthritis in adults is more amenable to radical surgical measures than in children. In this expression of opinion I am supported by many of the most recent writers on the subject, notably by C. F. Painter,[4] J. W. Sever,[5] and Augustus Wilson.[6] The last named goes so far as to say that "we now look upon the avoidance of surgical interference as most conducive to the recovery of the patient."

These remarks, then, apply not only to the cure of the disease, but to the question of complications, such as an affection of other joints and the onset of general tuberculosis. There is reason to believe, and some surgeons think they have evidence to show (J. W. Sever[7]), that frequent curettings have been followed by implication of other joints much earlier than when the case has been left alone. And some of us have been shocked from time to time by the sudden onset of tuberculous meningitis after a very trivial operation—e.g., scraping a finger which is the site of tuberculous dactylitis. The general complication has followed on the operation so quickly and so unexpectedly that it is reasonable to regard one as having a distinct causal relationship to the other.

TREATMENT OF ABSCESS.

Bearing all these points in mind I pass on to speak more specifically of operations, and I have been asked, amongst other points, to elicit your views upon the treatment of abscess. Its existence does not necessarily involve immediate evacuation. If the pus is deeply placed, and if the patient is placed at rest in good air, the fluid contents are sometimes absorbed, and the caseous matter becomes encapsuled. If, however, in spite of these measures, the abscess increases in size, its sac should neither be allowed to become adherent to the skin nor to open spontaneously, as an opening often forms in an undesirable position and is liable to septic infection.

As a general rule, I am strongly in favour of that form of treatment introduced by Ménard at Berck-sur-Mer and rapidly

[7] Loc. sup. cit.

coming into favour in this country, owing to the advocacy of M. Jacques Calvé and Mr. Gauvain. The details are fully given in THE LANCET,[8] and the article is worthy of the most careful perusal.

When pus continually re-forms it is generally due to the extension of bone disease or to loose sequestra, and the cause can be ascertained by means of Roentgen rays. Then I advocate opening the abscess, invariably by more than one incision so as to permit free access to the cavity and allow the pockets to empty. The fluid contents and the sequestra are removed without any violent scraping of the sac wall, which should be merely rubbed with a soft swab. Pure carbolic is then applied and left in for about a minute and washed out with absolute alcohol. The cavity is dried and closed immediately so as to obtain primary union. It frequently happens that a little fluid subsequently accumulates beneath one of the wounds. A sterilised probe is then inserted, the fluid pressed out, and the wound allowed to heal.

I venture to say that drainage-tubes are an abomination and a source of grave danger, as they involve the risk of secondary infection; and in the opinion of careful observers the activity of the tubercle bacillus is accentuated by the presence of pus-producing organisms. Further, there are grounds for saying that the onset of lardaceous disease is often determined by mixed infection.

The treatment of sinuses is always a matter of great difficulty. In 1908 injections of bismuth-paste were introduced, but as some patients were poisoned paraffin wax has been substituted. Its efficacy and its mode of action are still *sub judice*.

RADICAL OPERATIONS.

Passing on now to the question of more extensive operations for tuberculous arthritis, "I do not believe that there has ever been a surgeon who has had to treat few or many such cases who has not searched for a radical plan of procedure, for some way of shortening the treatment and lessening the destructive action of the infection."[9] "Occasionally we become enthusiastic temporarily over attempts to extirpate tuberculous foci in childhood. These radical operations, although commendable and to casual consideration reasonable, are not attended with such results as to lead the surgeon to persist."[10]

What are the tests of the success of operation? They are complete eradication of the disease from the parts and retention of perfect function. We must admit that nearly all operations fall short of these ideals. Too often cure by operation means mutilation of the part and sacrifice of its functions. This remark may require modification when we deal with what may be termed focal or para-articular lesions.

However, let us discuss what conditions call for erasion and excision of the joints of the lower extremity. As to the formal excision of joints, formerly done in great numbers, there is ample justification for the criticism that there is scarcely any operation which looks so promising and satisfactory on the operating table and proves so disappointing afterwards. The disease is not cured because the infection is either too extensive or is not entirely removeable; function is impaired or lost, and the patient is crippled by the deformity.

EXCISION OF HIP-JOINT.

As to excision of the hip joint, it has its opponents and its advocates. Of the former, Professor Howard Marsh is perhaps the chief in this country and has been most consistent; and of the latter, Mr. G. A. Wright is prominent. I feel myself compelled to say that the opponents are more numerous than the advocates, and their opinions appear to me more weighty and convincing, their prognostications as to the final result more exact.

If we refer to a recent text-book[11] we find the matter discussed *in extenso*, and it appears that excisions may be done only in those cases where the difficulty in obtaining treatment on those lines which are known to give the best results—namely, by prolonged rest for years in special institutions [such as the country branch of the Alexandra Hospital, the Sevenoaks Hip Hospital, the Treloar Hospital at Alton, and the Liverpool County Hospital[12]]—is found to be insuperable.

An excision of the hip is often an imperfect operation because of the involvement of the acetabulum and pelvis by the disease in such a way as to render its complete removal a matter of grave danger and often of impossibility. If there are points which have been impressed upon me by systematic examination by X rays of hip-joint cases coming under my notice, they are that primary disease of the acetabulum, formerly thought to be very rare, is not so; and that the number of cases of simultaneous involvement of both the femur and acetabulum is much greater than is thought. I begin to suspect that the total of the two conditions will prove to be not far short of 50 per cent. of the total number of cases.

One important point should always be kept in mind before performing the radical operation for tuberculous arthritis. We should satisfy ourselves previously that we are able to remove the diseased area *in toto* without destroying the functions of the part and without endangering our patient's life; and I ask, Has this always been possible when formal excision has been decided upon? An excision of the hip often proves to be an imperfect operation because the whole of the diseased part cannot be removed.

The final results of the operation have been ably set forth by Mr. Ralph Thompson.[13] He says:—

> Of 200 cases in which the hip-joint has been excised, 70 may expect to be the subjects of progressive disease, and of these 30 may be expected to die from continuation and spread of the disease; 55 will rank as partial failures, in that in them sinuses persist; 70 cases may look forward to a complete recovery; 2 cases, however, among these will have a flail-joint. The best result, a useful joint with free mobility and without sinuses, will fall to the lot of 25 of 200 people, or 1 in 8 of those operated upon.

Mr. Thompson has arrived at these conclusions from a study of 40 cases. In 2 cases more than 10 years, in 14 cases more than 5 years, in 4 cases more than 3 years, in 12 cases more than 1 year, and in 5 cases less than a year had intervened between the operation and the date of report.

I question if these results are better than those obtained by rest and splints. To some surgeons the presence of a tuberculous focus may be a temptation to operate. I suggest that it is better to deal with the conditions as they arise and try prolonged rest in the best surroundings. If abscesses appear, deal with them on the above lines. If sequestra form, localise them by means of X rays and remove them.

OPERATIONS ON THE KNEE-JOINT.

Of the two operations practised upon the knee-joint I regard erasion as much over-rated. If its objects are to eradicate the disease and to obtain movement in the joint afterwards, then I am prepared to affirm that, even in the event of cure of the disease, fibrous ankylosis and loss of movement follow, or else that the degree of movement is so small as to be useless. Frequently, too, the disease reappears, partly from the irritation to which the part is subjected in its deformed position; and, even if it does not do so, the tibia is so often displaced backwards and outwards, and the knee-joint is so bent as to render the limb an encumbrance rather than a help.

The less the operation partakes of the nature of an arthrotomy and the more it partakes of an erasion, the less useful is the limb afterwards. I have performed limited arthrotomy of the knee in cases of localised tuberculosis.

In one instance a tuberculous mass of the size of a pigeon's egg had formed in the infra-patellar pouch on the inner side, leaving the movements of the knee-joint entirely free. I dissected the mass from the sub-synovial tissue without opening the joint and the patient had a comparatively useful knee for three years. Then extensive involvement of the joint set in and excision was done.

The safest course in tuberculosis of the knee-joint is to give a long and patient trial to conservative treatment, and if this fails to give up all hopes of a moveable joint and do a formal excision, having regard to the epiphysial lines, and endeavour to secure sound bony ankylosis and a straight limb.

ANKLE AND FOOT.

If we pass on to the ankle and foot, these parts appear to present unusual facilities for operative treatment on tuberculous foci, and in many cases the results have been strikingly successful, especially when a single bone in the foot has been

affected, or there is a localised focus in the tibia or fibula. We have, however, to remember that when we come to operate the appearances seen by the X rays are always less severe than those we find on actual inspection, for the synovial membrane is frequently found to be extensively invaded.

Even in dealing with the ankle and foot, the statistics which are available show the best results are obtained by rest and conservative treatment. James Warren Sever[14] has given us comparative statistics on these points. 101 cases of disease of the ankle and tarsus were operated upon, including 45 excisions of the astragalus, 14 removals of the lower end of the fibula, and 11 removals of the lower end of the tibia. Good movement of the part followed in 29, slight in 22, none in 47. In only 7 was there no subsequent deformity. In 65 thickening remained about the malleoli; in 29 some definite distortion of the foot followed. The average duration of the disease from its onset, in the operative cases, until treatment was discontinued was 19·8 months—and of treatment itself 10·1 months.

For comparison, results in 88 non-operative cases are tabulated. Motion was good in 32, slight in 23, and none in 33. Deformity was entirely absent in 4, thickening was present in 63, and distortion was present in 21. The average duration of disease until cessation of treatment was 16·1 months in 99 cases; the average duration of treatment itself was 6·8 months, giving an average in favour of the non-operative series of 3·3 months from the beginning of the treatment until it was no longer necessary. The figures show that "there was a distinct gain in time, also in the function and lack of deformity of the foot in the non-operative series."

JOINTS OF THE UPPER EXTREMITY.

The joints of the upper extremity present problems differing from those of the lower. Whereas the chief functions of the lower limbs are stability and weight-carrying, those of the upper extremity consist of highly educated movements, and the importance of preserving them is undisputed. Operative interference, if it is likely to have the desired object, may therefore be considered at an earlier date than in the lower extremity. In children, however, erasion frequently proves to be better than a formal incision when conservative treatment has failed.

In the case of the shoulder-joint there is, however, an exception to be made. Other surgeons have noted the fact as well as myself that tuberculous arthritis of the shoulder-joint is frequently followed by pulmonary phthisis. In one case I noted the sequence of tuberculous arthritis of the shoulder: a dry apical pleurisy and phthisis, as if direct lymphatic extension had taken place. This observation may lead the surgeon to attempt eradication of the disease at the shoulder-joint at an earlier stage than would otherwise be the case.

FOCAL EXTRA-ARTICULAR LESIONS.

There are two points on which discussion may be profitably provoked—namely, the question of focal, extra- or para-articular lesions, such as are found in the great trochanter in children, and the treatment of tuberculous dactylitis.

As to the former, the point which advocates of operation should bear in mind is that there should be a sufficiency—as shown by X rays—of healthy bone between the lesion and the limits of the neighbouring joint. If there is not, any opening up of the vascular and cellular spaces often leads to arthritis; and of the comparatively few cases of this nature on which I have operated I may say that the disappointments and failure to save the neighbouring joint have exceeded the successes in the proportion of three to one.

TUBERCULOUS DACTYLITIS.

Tuberculous dactylitis has been shown by Ménard and others to be an exceedingly formidable type of disease. Disease of the spine more frequently complicates it than does disease of the larger joints, and it is responsible for an undue ratio of generalised tuberculosis.

Conservative and climatic measures should be carried out from the first, and if these do not give an early and satisfactory result amputation of the finger is desirable. The difficulty is to deal with these cases when the metacarpal bones are affected, with implication of the neighbouring tendon-sheaths. It is an obstinate and refractory lesion, but the same remarks apply to this operation as to operation for any other form of tuberculosis—namely, when conservative treatment has failed, and if an operation is done, let it be thorough.

[14] Journal of the American Medical Association, Dec. 16th, 1910, pp. 2128-33.

SUMMARY.

To sum up, the objects of every form of treatment of tuberculous arthritis must be: (1) To eradicate the disease; (2) to preserve the functions of the part; and the question is whether these results are more frequently obtained by climatic and conservative measures or by so-called radical operations. It appears to me that the balance of experience gained in treatment during the last decade shows that unquestionably conservative treatment is the better in childhood. Time is saved, the resultant deformity is diminished, and there is less risk of generalised tuberculosis when the treatment is non-operative.

THREE CASES OF ERYTHRÆMIA (POLYCYTHÆMIA), IN ONE OF WHICH THE TOTAL VOLUME OF THE BLOOD WAS ESTIMATED.

BY W. HALE WHITE, M.D. LOND. AND DUB., F.R.C.P. LOND.,
SENIOR PHYSICIAN TO, AND LECTURER ON MEDICINE AT, GUY'S HOSPITAL.

I HAVE recently seen the three following examples of this disease, known also as Osler's disease, Vaquez's disease, and splenomegalic polycythæmia, and because they each show features of interest they may be considered worthy of record. Unfortunately, they do not in any way indicate why the blood should hypertrophy to the extraordinary extent that it does in this condition. In none of them could any cause for the polycythæmia be discovered, and it was clear from the history of the first patient that the disease had begun only three years before I saw him, and then his attention had been called to it by his becoming dusky; in the other two the diagnosis was only reached by a routine examination of the blood of patients whose spleens were enlarged, for neither of them was cyanotic, and thus they illustrate that the disease should not be called "splenomegalic polycythæmia with cyanosis," as is sometimes done.

The noteworthy points in the first case were that the splanchnic vessels were apparently very distended, for the patient had much indigestion, was frequently sick, and almost certainly had hæmatemesis. This and the oozing of blood from the gums no doubt gave some temporary relief, as venesection may. The appearance of many little patches of dilated venules on various parts of the skin and the dilated vessels of the conjunctiva may also be regarded as evidence of the extreme distension of his veins, which, too, was well shown on ophthalmoscopic examination. Other observers have noticed the appearance of the fundus oculi. Judging by this case, I should say it would always be easy to recognise. It would be interesting to know if the other two patients will become cyanotic later. In the first patient the urine contained a little albumin and a few casts and a few red cells, this harmonising with the hæmatemesis and oozing from the gums. These characters of the urine might easily lead to an incorrect diagnosis of chronic nephritis; indeed, this had been the diagnosis in this case before the blood was examined, but the arteries, the heart, and the blood pressure were normal—a remarkable fact considering the enormous volume of blood, for the determination of which we have to thank Dr. C Gordon Douglas. The volume was three times the normal and the red cells were double the normal per cubic millimetre, which means that the patient had in his blood six times the normal number of red cells, and the total amount of hæmoglobin was about four times the normal. The number of white cells per cubic millimetre was half as much again as normal (the increase, as usual, being in the polymorphonuclear cells, which formed 84 per cent. of the total white cells), so that the total increase of white cells was about four times the normal. Such blood must nearly have reached a volume and density which would render the circulation very difficult. It will be noticed that the specific gravity was very considerably above the normal—viz., 1076. Considering the very high oxygen capacity of the blood a complete metabolism experiment extending over a long period

ought to be carried out on a case of erythræmia. It is noteworthy that the patients in Cases 1 and 2 lost weight—there was no information as to weight in the third case, which was of mild character, and this may have been due to disordered metabolism, but then the indigestion associated with the overful splanchnic vessels has to be borne in mind. None of the patients were excessively hungry.

The great point of interest about the second case is that an extreme hypertrophy of an accessory spleen, combined with a moderate enlargement of the spleen, led to the formation of an abdominal tumour of such a shape that none who saw the patient thought the tumour could be a spleen. The excessive oozing after operation indicates an overful vascular system, but by no persuasion could we get the patient to submit to examination of her blood so as to estimate the total quantity. The last count showed double the normal number of red cells and four times the normal number of white cells per cubic millimetre. Probably there is not a great increase of the volume of the blood in the case, for the patient is not cyanotic.

The third is not a severe case. It is of interest that the patient had had an exploratory laparotomy, so presumably at some period of her illness there was some doubt as to whether the abdominal tumour was a spleen. She is probably progressing slowly, for the red cells are but 8,000,000 per cubic millimetre and the white cells are not yet increased, nevertheless the spleen is larger than in either of the other two cases.

CASE 1.—The patient, who lived chiefly in one of our colonies, came to England for a few weeks on business. He was 42 years old. He had always been absolutely well till three years ago when he began to suffer from indigestion and his face began to get a deep colour, so that some of his friends chaffingly said he had been too convivial; others that he had taken too long a holiday in the sun. Neither of these suggestions was true. During the last three years the indigestion has increased, and several little groups of dilated venules (telangiectasis) have appeared in various parts of the skin. The patient has lost a stone in weight and has been frequently sick, and from his description of the vomit I think there is little doubt that it contained blood, but he was not sick during his stay in this country. He is also liable to bleed considerably from his gums. Dr. C. H. Mollison, of Melbourne, found 10,700,000 red cells. When I saw the patient he had a full-blooded livid look, especially noticeable on the face, but evident all over him. The heart and lungs were healthy; the spleen reached to the umbilicus; the liver was just palpable; there were no enlarged lymphatic glands; the gums were bleeding, and the tongue was clean but livid. The urine had a specific gravity of 1015; there was no sugar, but a very small amount of albumin. The slight deposit contained a few hyaline and finely granular casts, a small number of red cells, and some leucocytes; there were no crystals. An examination of the blood showed: red cells, 9,800,000; no poikilocytosis; no polychromasia; no nucleated or other abnormal cells; white cells, 15,300; small lymphocytes, 7 per cent.; large lymphocytes, 7 per cent., polymorphonuclears, 84 per cent.; eosinophiles, 2 per cent.; hæmoglobin, 131 per cent.; colour index, 0·67; specific gravity, 1076; blood pressure, 130. The eyes were blood-shot; there was a little conjunctivitis. The ophthalmoscopic appearances were striking, for the veins were obviously overful and the blood in them was of a very dark-blue reddish tint. It seemed to me the appearance was such that I should recognise it again as characteristic of the disease, and in this my ophthalmic colleague, Mr. H. L. Eason, agreed with me. Fortunately the patient was interested in his case and he willingly made a journey to the physiological laboratory at Oxford, where Dr. Gordon Douglas, to whom I am much indebted, kindly estimated the total volume of blood by the Haldane and Lorrain Smith method, with the following result: Weight of patient in clothes, 126 lb.; naked, approximately 114 lb., or 51·8 kilos. Hæmoglobin percentage (Haldane scale) = 140, equivalent to an oxygen capacity of 25·9 c.c. per 100 c.c. of blood. Amount of CO given at standard temperature and pressure = 220 c.c., giving a percentage saturation in the blood of 8·4. Total capacity of the blood for oxygen (muscle hæmoglobin counted as if it were blood hæmoglobin) = 2620 c.c. Total volume of blood calculated from the total and percentage oxygen capacities = 10,200 c.c. Oxygen capacity per 100 grms. body weight = 5·06 c.c. Blood volume per 100 grms. body weight = 19·7 c.c. Red cells per c.m. = 9,720,000. For comparison with this:—Douglas (average during several months): weight, 61·5 kilos.; red cells, 4,890,000; hæmoglobin, 98·8 per cent. = 18·3 per cent. oxygen capacity. Total oxygen capacity = 830 c.c. = 1·35 c.c. per 100 grms. body weight. Blood volume = 4566 c.c. = 7·43 c.c. per 100 grms. body weight. Haldane (average during several months): weight, 79·5 kilos.; red cells, 4,670,000; hæmoglobin, 100·6 per cent. = 18·6 per cent. oxygen capacity. Total oxygen capacity = 902 c.c. = 1·13 c.c. per 100 grms. body weight. Blood volume = 4821 c.c. = 6·06 c.c. per 100 grms. body weight. It will be seen that the patient had roughly four times the normal amount of hæmoglobin and three times the normal amount of blood for a man of his weight.

CASE 2.—An unmarried woman, aged 57. She said she had in the past suffered from neuritis and erythema. She looked a trifle pale and drawn and had lost 2 st. in weight within a comparatively short time. She now weighed 9 st. 0¼ lb. Her height was 5 ft. 5 in. She had complained of much severe irregular abdominal pain and some flushing of the hands. A large very irregular tumour could be felt in the abdomen at the left and upper part. At no time had it felt at all like a spleen. Several consultations had been held, and as it was extremely difficult to determine the nature of the tumour or even the organ in which it originated an exploratory laparotomy was decided upon and I was present at the operation. The tumour felt was found to be a moderately large spleen, the notch of which was just under the ribs and could not therefore have been felt through the abdominal wall; close to the anterior margin of the spleen was an accessory spleen, disc-like and extending forwards to the middle line. It was considerably enlarged, being rather larger than a five-shilling piece. It was this combination of enlarged spleen and enlarged accessory spleen that gave an abdominal tumour of such a shape that none of the medical men who saw the patient before operation thought it was a spleen, although the possibility had been remembered. There was some capsulitis both of the spleen and the accessory spleen. There was an exceptional amount of oozing of blood for 72 hours after the operation on August 27th, 1911. A few days after the operation a blood count made by Dr. Alfred C. Coles showed: red cells, 7,375,000; white cells, 43,400; hæmoglobin, 90 per cent.; colour index, 0·6. The red cells were normal in appearance. A second count three weeks later (Sept. 18) showed: red cells, 7,880,000; white cells, 27,400; hæmoglobin, 95 per cent. The patient felt much better after the operation and gained weight. Dr. Coles did a third blood count on Dec. 14th, 1911, and found red cells, 9,546,600; white cells, 46,350; hæmoglobin, 117 per cent.; colour index, 0·66. He reports as a result of an examination on that day: "No cyanosis; there was some dilatation of vessels, but not enough to suggest the condition. The spleen now reached 4¼ in. below costal margin."

CASE 3.—The patient, aged 28, was admitted into Miriam Ward, Guy's Hospital, under my care on Nov. 13th, 1911, and subsequently was transferred to Mary Ward. She had been quite healthy until three years ago, when she first noticed pain and discomfort in the left side of the abdomen, sufficient to prevent her from doing her housework. Eighteen months ago the abdomen was opened at another hospital and the tumour which had been previously felt was found to be an enlarged spleen. As the abdominal discomfort continued she came into Guy's Hospital. There was nothing abnormal in her appearance—in fact, all that could be detected wrong after a very complete examination was that her spleen, which was easy to feel, reached down to 2 inches below the level of the umbilicus and forward to within an inch from the umbilicus. The enlargement of the spleen led us to examine the blood with the following result: red cells, 8,600,000; white cells, 7000; polymorphs, 62 per cent.; large lymphocytes, 24 per cent.; small lymphocytes, 12 per cent.; eosinophiles, 2 per cent.; hæmoglobin, 100 per cent. A second blood count done a few days later gave red cells 8,000,000 and white cells the same as before. The blood pressure was 134 millimetres of mercury. Examination of the optic disc showed nothing abnormal. The temperature and pulse were normal for the ten days during which the patient was in the hospital. There was no evidence of syphilis and nothing of importance in the family or personal history. Unfortunately

no persuasion that we could bring on her could make her yield to our request that we might take the total volume of her blood.

Wimpole-street, W.

SOME POINTS IN THE DIAGNOSIS AND TREATMENT OF CHRONIC DUODENAL ULCER.

BY B. G. A. MOYNIHAN, M.S. LOND., F.R.C.S. ENG.,
PROFESSOR OF CLINICAL SURGERY, UNIVERSITY OF LEEDS.

IN THE LANCET in 1910[1] there appeared the paper with which I opened the discussion at the Royal Society of Medicine upon Duodenal Ulcer. In the time that has passed since then certain features of this disease, in respect both of diagnosis and of treatment, have been made clearer and their relative values more accurately determined. In so far as the diagnosis of the disease is concerned the statement remains true, after all the arsenal of argument delivered against it, that it is upon the clinical history of the case we chiefly rely for accuracy. The anamnesis which was fully recited in the paper to which I refer, if considered in *all* its details, is so characteristic that a diagnosis of duodenal ulcer based solely upon it will very rarely prove inaccurate when the parts are examined at the time of operation. I emphasised also the fact that the duodenal ulcer, whose presence had been predicted upon the strength of the history alone, could be demonstrated to the conviction of all; that the ulcer was a real and not a fanciful thing. Perhaps the chief criticism to which that paper was subjected, and certainly that which had been most confidently expected, was that the picture of the disease drawn therein did not differ notably from that which had been recognised by generations of physicians as due to "acid gastritis" or "hyperchlorhydria."

When first we began to disentangle the authentic symptoms of duodenal ulcer, and by degrees to recognise clearly the well-defined clinical picture of this disease, I was struck with the similarity, indeed in some respects the identity, of the symptoms recited to me by the patients to those described by the most authoritative writers on medicine as due to "hyperchlorhydria." And when repeatedly I found that cases diagnosed by physicians of the first rank, well versed in the literature and of much practical experience, as "hyperchlorhydria" were in fact cases of duodenal ulcer, and would so be demonstrated upon the operation table, I felt entitled to claim that in the diagnosis of such cases the physician walked by faith and the surgeon by sight. And when, further, it was found that in a series of such cases an excess of free HCl was not present in the majority, it became quite certain that there had been confusion not only in terms but in the whole conception of the cases. A genuine organic disease was miscalled "functional." My own experience of the relationship of hyperacidity to duodenal ulcer, in all the phases in which we meet it upon the operation table, from early active ulceration to the final cicatricial stenosis, is roughly this: that in about 40 per cent. of the cases free HCl is in excess, in 40 per cent. it is approximately normal, and in 20 per cent. it is below the normal. It may be that there is a geographical factor in the different experiences of different authors in their examinations of the amount of free HCl. Dr. A. F. Hertz has drawn my attention to the fact that at the discussion on the treatment of gastric ulcer at the German Congress for Internal Medicine held in Wiesbaden in 1909, Lenhartz, of Hamburg, von Müller, of Munich, and von Krehl, of Heidelberg, laid stress upon the differences in the results of analysis of the gastric juice in patients suffering from gastric ulcer in different localities. In Munich, for example, hyperacidity is exceptional, and in at least 20 per cent. of the cases there is hypochlorhydria. In North Germany, on the other hand, hyperchlorhydria is almost constantly present in gastric ulcer. In France, or at any rate in Paris, hyperchlorhydria appears to be almost constantly present in gastric ulcer. In this discussion, however, the possibility, indeed the strong probability, that the diagnosis in many cases was erroneous cannot be ignored. The work of the surgeon has shown how very difficult the accurate diagnosis of gastric ulcer always is.

[1] THE LANCET, Jan. 1st (p. 20) and 15th (p. 173), 1910.

Dr. G. A. Gibson[2] mentions a series of cases of duodenal ulcer proved by operation in which he found that the total acidity varied from 0·01 per cent. to 0·26 per cent. The amount of free acid varied between 0·02 (very small) and 0·18 (extremely high); so that Dr. Gibson's experience shows that "in undoubted duodenal ulcer the condition of acidity in the stomach varies within wide limits."

Dr. F. Craven Moore, who has devoted a great deal of attention to the chemistry of gastric and duodenal disorders, considers it essential that no less than three separate examinations of the stomach contents should be made at intervals of a few days, and that the averages of these three should alone be considered. If his contention is justified, as it probably is, then the work of many investigators must be set aside. Dr. Craven Moore has examined the stomach contents in a series of cases in which duodenal or gastric ulcers were actually demonstrated upon the operation table, and in every case of the former disease an excess of free HCl was found.

It is now well known that hyperacidity may be present when symptoms quite different from those described in many of the text-books are elicited in the history, or even when no gastric symptoms whatever are present. Hyperchlorhydria is found, fleetingly, in cases of cholelithiasis; it is present in cases of gastric ulcer, of colitis, of tuberculous disease of the intestine or of the mesenteric glands, and of appendicitis. H. J. Paterson, who has consistently and closely studied the gastric chemistry in cases requiring surgical treatment, writes that he has "operated upon nearly 50 cases of hyperchlorhydria, and in every one of them there was an organic lesion either of the stomach, duodenum, gall-bladder, or appendix."[3]

I have no doubt that the different disclosures as to the quantity of free or active HCl in the stomach contents related by various observers may be in part due to the different stages of the disease in which the examinations are conducted. If the ulcer is active, the patient being in the fury of one of his "attacks," free HCl is probably present in excess in the majority of the cases. If the "attack" is over, or if the symptoms the patient presents are those of a stenosis which has at last developed at the site of a chronic ulcer, then the free HCl may be diminished or be absent.

The whole question may, I think, be summed up in this way. Hyperchlorhydria, a term which has been debased and shorn of its original significance, should not be used in a clinical sense, but should be held strictly to indicate the excess of active hydrochloric acid in the stomach contents.[4] Hyperchlorhydria is present in most cases of duodenal ulcer during the active stage of ulceration. There may be hypochlorhydria in cases of duodenal stenosis; in the intervals between "attacks"; or, rarely, in the acute phases of ulceration. There are possibly geographical differences in the frequency and severity of hyperchlorhydria in cases both of duodenal and of gastric ulcer. Hyperchlorhydria is present in other diseases, notably cholelithiasis and appendicitis, and its presence probably explains the mimicry of the symptoms of duodenal ulcer by these various diseases. The persistent presence of an excess of active hydrochloric acid in the stomach contents is indicative of an organic rather than a functional disorder.

During the last two years the majority of my cases of duodenal ulcer have been examined by the X rays after the administration of a meal of bismuth, with milk or bread and milk. The results which Dr. L. A. Rowden has obtained have been interesting. As a rule, in uncomplicated cases of duodenal ulcer—that is, in cases where obstruction has not yet developed—a most striking spectacle is afforded by the greatly increased activity of the stomach. Food begins to pass into the duodenum at once, and continues to pass with greater rapidity than in the normal condition. By the time the pain begins to appear the stomach is nearly empty, and most of the bismuth has left the duodenum through which it shoots rapidly, and can be seen in the small intestine. The muscular activity of the pyloric portion of the stomach is exalted. In a few cases a local arrest of the bismuth in the first portion of the duodenum has led Dr. Rowden correctly to predict the presence of a pouch caused by the distorted contraction of an ulcer, in the manner first described by Perry and Shaw. In very few cases there has been some delay in the emptying of the

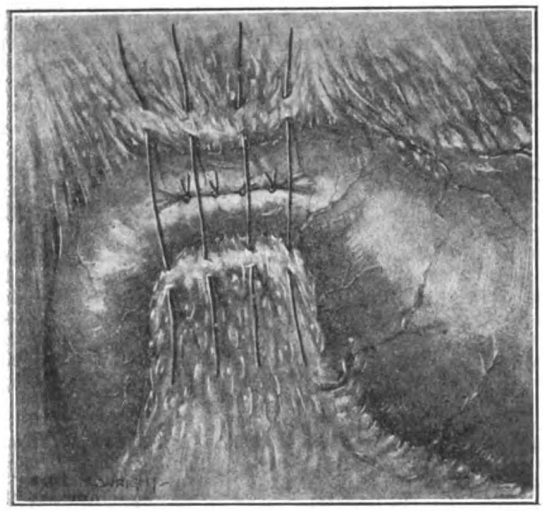
[2] Edinburgh Medical Journal, 1911, vol. vi., p. 325.
[3] Proceedings of the Royal Society of Medicine, 1910, vol. iii., p. 108.
[4] See Willcox: Quarterly Journal of Medicine, 1909, vol. iii., p. 9.

duodenum. I am not prepared to say that this condition of excitable and vigorous peristaltic movement in the pyloric antrum is characteristic of duodenul ulcer, but there is no doubt that it is almost constantly present. Further inquiry is needed, however, to discover what the activities of the stomach are in those examples of disease of the mid-gut in which its quick sympathies are aroused. This "hypertonic" condition of the stomach had been previously recognised by Dr. Hertz [5] and Dr. A. E. Barclay.[6]

In order to obtain some idea of the frequency of the passage of occult blood in cases of duodenal ulcer I had 20 cases in succession examined during the course of the year 1911. In all a duodenal ulcer was diagnosed, in all one or more ulcers or large scars were found at the time of the operation. The fæces were examined in every case by Dr. M. J. Stewart. In 10 cases blood was found in the fæces; in 2 of these it was plainly visible to the naked eye. In 10 cases it was reported that no blood was present; in 3 of these a history of melæna was given by the patient or his medical man. It is probable, however, that in cases of active ulceration in the duodenum a daily examination of the stools would reveal the frequent, if not constant, presence of blood. Dr. Craven Moore has found occult blood in 100 per cent. of his personal cases.

The diagnosis of duodenal ulcer, therefore, depends upon, first and foremost (indeed almost exclusively), the anamnesis. The history, set forth in detail in my former paper, enables a diagnosis to be made with a risk of error which, when tested by the operation, is found to be extremely small. Secondly, the discovery during the stage of active ulceration, during

FIG. 1.



Showing a duodenal ulcer infolded by sutures which are tied and cut short. The four long sutures (or ligatures) when tied draw the omenta over the duodenum and completely cover it.

the "attacks" that is, of an increased secretion of free HCl. Thirdly, the striking and possibly characteristic picture given upon X ray examination after a bismuth meal. The stomach, in the presence of active ulceration in the duodenum, seems to have an enhanced activity in respect both of its secretory and of its motor functions. Fourthly, the discovery of occult blood in the fæces during the stage of active ulceration, if daily examinations of the fæces are made. In the later stages, of course, the appearances due to slight or severe stenosis may be presented. The physical signs elicited upon an examination of the abdomen are only of the slightest value until such obstruction has developed.

So far as the surgical treatment of chronic duodenal ulcer is concerned, there can be no doubt that the only operation appropriate for the great majority of the cases is gastro-enterostomy. In 12 cases of solitary ulcer I have performed excision only; all the patients have remained perfectly well since the operation. In the remaining cases (361 in number) I have performed the short-circuiting operation. The anastomosis is made upon the posterior surface of the stomach and the jejunum is applied in the vertical direction. The after-histories of all the cases operated upon to the end of 1910, prepared by Mr. Harold Collinson, will soon appear in detail in the second edition of my book "Duodenal Ulcer." They show that the immediate mortality is small, about 1·3 per cent., and that the late results leave little to be desired. The experience of many surgeons proves, however, that gastro-enterostomy alone is not enough to make certain of complete immunity from disaster. Both perforation and hæmorrhage have occurred many weeks or months after the apparently successful performance of this operation, and have proved fatal. I consider, therefore, that a local treatment of the ulcer is essential, and this, I believe, is best carried out by the infolding of the ulcer in precisely the same manner as would be adopted if the ulcer had perforated. A few Lembert sutures taken vertically, or transversely, from one side of the ulcer to the other cause the ulcer to be buried when they are tightened. It is desirable that the stitches should under-run any conspicuous vessels leading to the ulcer, so that the circulation through them is checked. After this has been done I now always cover the duodenum by the aid of a few ligatures or stitches, taking on the one hand the gastro-hepatic omentum and on the other the gastro-colic omentum in such manner as to fold these structures over the bowel, and so to form a secure investment and protection for it (see Fig. 1).

It is essential in all cases of duodenal and gastric ulcer, when the condition of the patient warrants it, that the appendix should be examined. The frequency with which it is grossly diseased is astonishing. To illustrate this frequency and the degree of the changes which are found I have asked Mr. L. R. Braithwaite to reproduce for me the drawings which he made from the first cases we operated upon together in the year 1911 (Fig. 2). The appendix was examined and removed 12 times in 14 consecutive patients. In the remaining two cases the patient was so ill that I was unwilling to add any risk, however trivial, to that which we were compelled to run. This period and this number were selected quite arbitrarily, without any thought of what the result might be. Mr. Braithwaite, who helped me with the operations, drew the exact conditions found within a few minutes of the removal of the appendix, and his drawings are exactly reproduced here. The appendix shows some evidence of disease in every case, and in three the little tube was found to be divided into two parts entirely separate from one another. This condition of complete, or almost complete, severance of the appendix is one which appears to be unknown; in one case I found the separation to be about 1½ inches. It is important to remember the possibility of this division, more especially in those cases when the appendix seems unusually short. We examine and remove the appendix in, approximately, 9 out of 10 of all cases. In 80 per cent. of those removed there are evidences of long-standing and advanced disease.

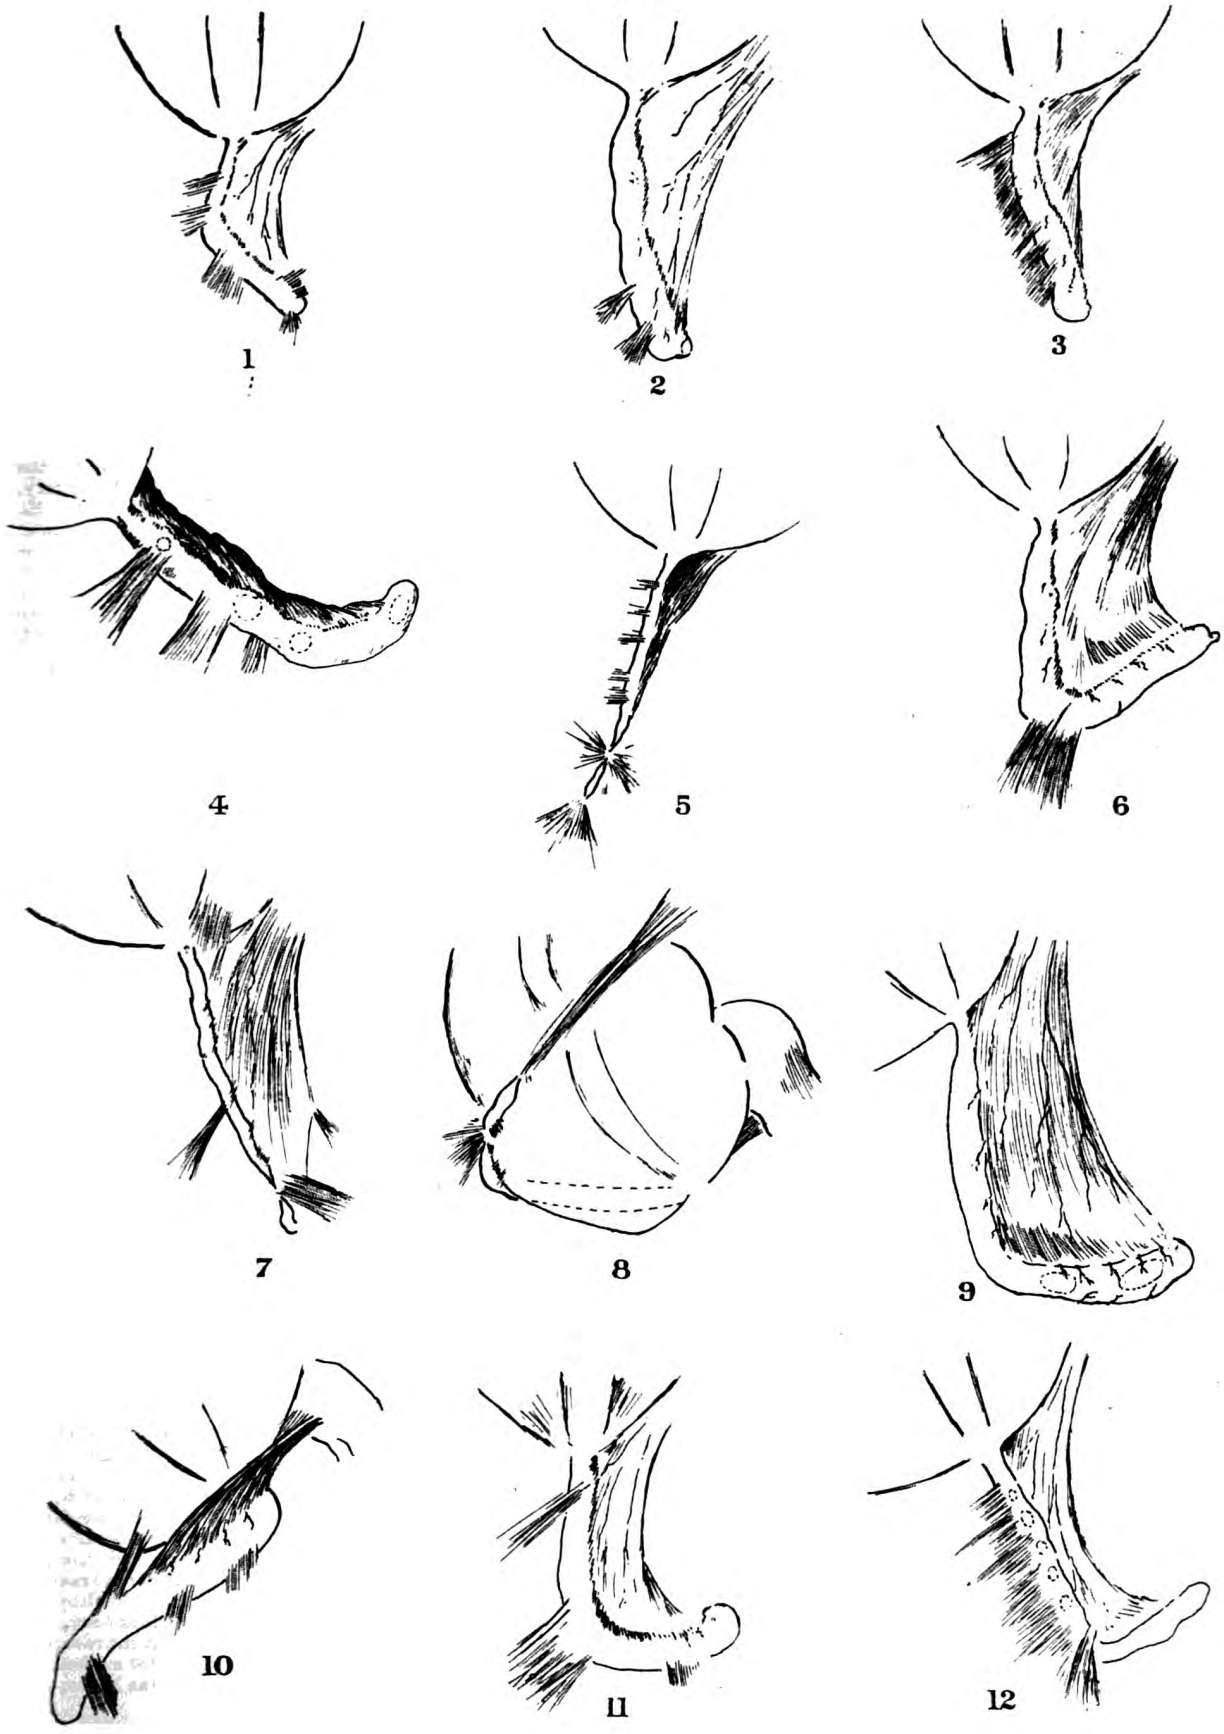
I have long held the view that the diseases of the stomach, duodenum, and gall-bladder with which the surgeon deals are not primary but secondary. They are the result, in my opinion, of an infection or of a toxæmia which has its origin for the most part in some abdominal organ. The experimental work of Turck, of Wilkie, and others strongly supports this view, as does also the knowledge we have of the development of acute ulceration of the duodenum in cases of burns, uræmia, pemphigus, erysipelas, operations upon the genito-urinary organs, and many other intensely infective conditions. The evidence has seemed to me to be strongly in favour of supposing that the source of infection in many of the cases of chronic ulcer is in the appendix; in some it is in the small

[5] The Sensibility of the Alimentary Canal, 1911, p. 59.
[6] Archives of the Röntgen Ray, 1910, p. 123.

DESCRIPTION OF FIG. 2.

Drawings of the appendix *in situ* in 12 out of 14 consecutive cases operated upon for gastric or duodenal ulcer at the beginning of 1911. All, except No. 9, show extensive adhesions. No. 9 was markedly congested in its terminal inch and a half and contained two solid bodies in this part. Nos. 4 and 12 contained many solid bodies. Nos. 5, 7, and 8 are most interesting; in these the appendix is divided by fibrous bands into two distinct and separate pieces. Nos. 6 and 12 show diverticula. In all, except No. 7, there was a duodenal ulcer present; in No. 7 the ulcer was on the lesser curvature of the stomach, and in Nos. 8 and 11 there were both duodenal and gastric ulcers. Lane's ileal kink was not present in any case. The dotted circles represent foreign bodies. (Drawn by Mr. L. R. Braithwaite.)

FIG. 2.



intestine, in some in the large, in some in the pelvic organs of the female, in some in parts outside the abdomen. A routine examination of the abdomen should follow the direct dealing with the stomach in all cases of duodenal ulcer, if the patient's condition permits this to be done with safety. It is remarkable with what frequency one then discovers a serious lesion in the appendix. I therefore make it a practice, with few exceptions, to examine and remove the appendix in all cases of gastric and duodenal ulcer and of gall-stones.

In a very small proportion of the cases the kink in the lower end of the ileum described by Arbuthnot Lane is found. It is generally not of much obvious importance in so far as the impediment to the onward passage of intestinal contents is concerned. But in all cases it is best to divide it, and by a few stitches, or by the smearing over of sterilised vaseline, to endeavour to prevent its re-formation. It is certain that in my earlier cases I overlooked the presence of "Lane's kink" in some instances, for it is only recently that I have made invariable search for it. In the last 87 cases of duodenal ulcer it was present four times. In about one-third of my cases a long meso-colic band, or some slender adhesion, is found attaching the jejunum to the under surface of the meso-colon. The purpose of the ligament of Treitz is surely to allow a very mobile portion of the intestine continuous with an absolutely fixed portion, so to move from side to side, in any direction, that no kink or obstruction is produced at the point of junction. It is extremely rare to find in cases of duodenal ulcer any evidence, either on X ray examination or upon the operation table, of an obstruction of any grade at the duodeno-jejunal flexure.

The importance of recognising the associated if not causal chronic inflammation of the appendix in cases of gastric and duodenal ulcer may be greater than at first sight appears. The days when the surgical treatment of disorders of the stomach was deferred until it seemed certain that the patient was otherwise likely to die are long gone by; the surgeon may now claim that his art has so far advanced that it is the means, not alone of saving life, but also, and chiefly, of loosening the cords of affliction in which so many are bound. The immediate mortality of any operation in cases of chronic duodenal ulcer is very small (less than 2 per cent.), and it is now our chief concern to ensure, if we can, that the future of the patients is free from any risk that may even remotely attach to the operation itself. Probably no operation in surgery which deals with any disease of equal severity can show results surpassing those of gastro-enterostomy in cases of duodenal ulcer. But one very serious, though exceedingly infrequent, blemish is found in the after-results: it is the development of a jejunal or gastro-jejunal ulcer in close proximity to the new anastomosis. If it is admitted that the hypothesis connecting the onset of a duodenal ulcer with the chronic infection discovered in the appendix is supported by the evidence, then it must also be conceded that the incidence of a jejunal ulcer may in like manner be determined by the continuance of that infection when the appendix is allowed to remain.

Leeds.

A SERIES OF
TWELVE FOREIGN BODIES REQUIRING SURGICAL INTERFERENCE.

BY RUSHTON PARKER, M.B., B.S. LOND., F.R.C.S. ENG.,
PROFESSOR OF SURGERY IN THE UNIVERSITY OF LIVERPOOL.

THE literature of foregn bodies is fairly abundant, being copiously epitomised in surgical handbooks, and having to itself a work of 780 pages by Dr. Alfred Poulet.[1] All these publications are instructive as references and aids to practice, but they can never be exhaustive, as from time to time isolated experiences of great curiosity and rarity, sometimes giving rise to marked ingenuity, continually come to light. Pictorial illustrations have not been wanting, though afforded in only a few of the vast host recorded.

From their nature foreign bodies have an interest which is very varied. Some are mere curiosities which may have an amusing side; others, while strange and unexpected, are chiefly notable for the little harm they have done; others again, though commonplace, are elevated into notoriety by the dangers or tragedies that result. The accompanying illustration shows a number of foreign bodies the interest of which is apparent at sight, and will, it is hoped, justify their publication.

No. 1 is part of a knife-blade, 2¼ in. long and over ¾ in. broad, broken off and embedded in the left pterygomaxillary region of a sailor. He was stabbed on a voyage from New York to Liverpool, but continued at work on board ship, having no greater inconvenience than gradual stiffening of the jaws, and closure to within half an inch, with pain on movement and some looseness of the left upper molar teeth. At the same time he felt sure that a piece of the knife remained. On arrival he was admitted into the Northern Hospital where Mr. Chauncy Puzey found a sinus, revealing metal on probing. He reopened the wound and drew out the knife, so firmly stuck as to require much force, 17 days after injury. No further harm resulted and the man left in a few days.

No. 2 is a piece of wood, 2½ × ½ × ¼ in., embedded in the right pterygomaxillary region of a man who was struck below his right eye by a bundle of planks that were being hoisted during the building of a house. The wound was stitched and dressed at the Liverpool Royal Infirmary, and nearly healed. But a sinus was left, with eversion of the eyelid, for which he went to the Eye and Ear Infirmary, where probing revealed what seemed to be loose bone. He was sent back to the Royal Infirmary, where he came under my care. Finding the same loose object, I gave the house surgeon who had first dressed him the opportunity of removing it, which he did in my presence. Instead of bone he pulled out a piece of deal, of prismatic shape and the above dimensions, as clean-looking as if fresh or just washed. Healing quickly occurred and no further harm resulted.

No. 3 is also a piece of wood, very similar to No. 2 in shape and size, broken off a chrysanthemum stick which penetrated and broke off in the mouth and cheek in front of the upper jaw of a boy aged 9 years, who became thus impaled while falling in his mother's greenhouse. The object was pulled out the same day by Mr. R. T. Hughes, of Birkenhead, who asked me to see the boy with him next day in case there seemed likely to be cause for anxiety or need for special precaution. All seemed still well, and so continued without further interference.

No. 4 is a wooden meat-skewer, the pointed end of which stuck in the anus, and was removed a few hours later by Mr. C. W. Dean, of Lancaster, on exploring under chloroform. The patient had eaten some cold mutton, but had no idea that with one of the slices an inch of skewer tip had been included and swallowed. On further search in the larder another piece of the same skewer, 1½ in. long, was found in the remains of the meat. The sloping cut edges of the divided skewer fitted exactly, and on the removal of the offending piece the patient felt no further trouble.

No. 5 is the breech of a muzzle-loading gun which burst and shattered the face of a young farmer. The wound healed with no outward deformity except a fœtid sinus under the upper lip and one in each nostril. After five years a loose object was felt and thought to be necrosed bone. The nostrils were entered under the upper lip by separating the nasal cartilages from the maxillary bones, and after some difficulty the objects—a gun breech and iron bolt—were separately removed. Rapid recovery followed. The case was reported in THE LANCET of Feb. 28th, 1885 (p. 378), with a wood-cut illustration, upon which the present exact photograph is an improvement. The dimensions are 3 × 1½ × 1 in. and weight 3½ oz. The patient was brought to Liverpool by Mr. O. W. Griffith, of Pwllheli, who assisted me at the operation in private lodgings.

No 6 is a piece of parasol rib, 3. in long, of the old-fashioned round wire variety, which entered, and was broken off in, a woman's forearm, where it remained 12 days. Her husband was attacking a cat which had killed one of his pigeons, a child's parasol being the first weapon at hand. In preparing a violent lunge at the cat his back-stroke drove one of the parasol ribs into his wife's forearm instead. The rib broke at the point of entry, leaving a piece inside. The deformity produced led the case to be taken for a fracture of the forearm by the house surgeon or student who first attended to the woman at the Liverpool Royal Infirmary, and accordingly put on splints. But when the patient returned among the out-patients the nurse reserved her for my inspection. There did appear to be a bend in one of the bones, but

[1] Traité des Corps Etrangers en Chirurgie, Paris, Octave Doin, 1879.

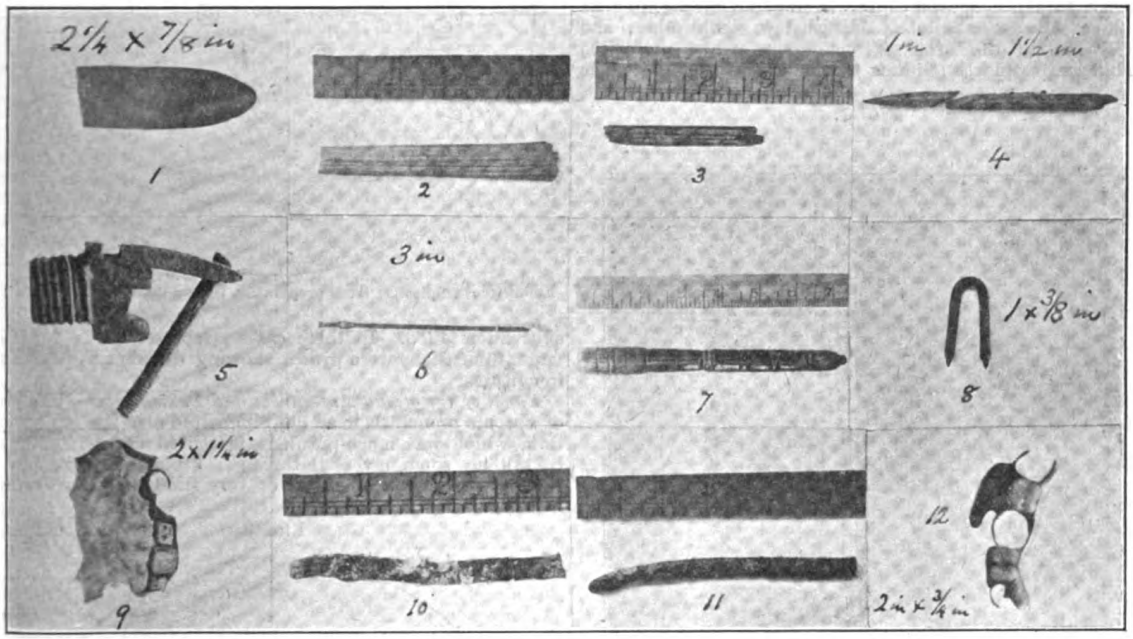
the patient's tale included the incident of the cat and the parasol rib, which was then easily felt, cut down upon, and removed without anæsthetic or further complication.

No. 7 is a remarkable specimen in a remarkable case. The object is a piece of turned oak, 7¼ in. long and from ½ to ¾ in. thick, called a "knitting sheath," used by women in some parts of the country, stuck in the girdle or apron-string as a rest for a long steel knitting needle. The blunt end of the "sheath" lies upwards, and has a hole over an inch deep in which the lower end of one needle rests to avoid wearing holes in the clothes of the knitter. A farmer, aged 70, stated that while stooping on his kitchen floor before a looking-glass trying to apply ointment to his anus with the narrow end of this stick to relieve itching, he fell over and the "sheath" entered his rectum and he could not get it out! After a fortnight's lodgment of the object he applied in the year 1888 at the Liverpool Royal Infirmary, where, with lithotomy forceps, I removed it without anæsthetic or detention of the patient. This was my first introduction to the strange, but no doubt useful, weapon here depicted.

crushed and washed away in dust and larger fragments to over 40 grains. A piece of catheter ¾ in. long was brought away in the blades of the lithotrite during the crushing. As more evidently remained, the rest, 2½ in. long, was fished up and pulled out through the urethra. The two pieces are here joined together on a wooden match.

Several instruments have been devised for the express purpose of extracting foreign bodies from the bladder by way of the urethra; but nothing seems to serve this purpose better than, or even so well as, a lithotrite, especially with smooth blades. Both French and English surgeons have found the lithotrite useful for the purpose, and in the present case no difficulty was felt.

No. 12 is a tooth plate, 2 in. long and less than an inch wide, which passed well down the œsophagus and could not be dislodged by exploring through the mouth. The case occurred in 1899 in a soldier aged 26. The plate was found to be so far down that I imagined it could be extracted through the stomach, and so the inconvenient and always dangerous œsophageal wound in the neck be avoided. But



No. 8 is an iron staple, 1 × ⅜ in., swallowed by a boy aged 9, and retained for four days, after which it was passed. Some griping was caused, and the staple was shown by X ray photography in the lower abdomen the day before issue; it was previously also identified by comparison with another specimen brought with the boy to the hospital, where he rested in the interval.

No. 9 is a tooth-plate, apparently of silver, 2 × 1¼ in., from a man aged 36, who woke up about 4 A.M. with this sticking in his throat. He came to the Liverpool Royal Infirmary in March, 1881, where I felt it with my finger in the lower part of the pharynx, and removed it with forceps through the mouth after lodgment of not more than nine hours. A drawing was made at once by Mr. J. R. L. Dixon, then a student, and the plate was restored to the patient, who put it back into his mouth and left. This illustration is a photographic reproduction of the drawing.

Nos. 10 and 11 are red rubber catheters broken off in the bladders of two elderly men suffering from prostatic retention and irritable bladder. No. 11 was found on opening the bladder by perineal urethrotomy, and requires no further remark. In No. 10 a farmer from Wales, aged 70, had four months previously broken off a piece of catheter in his bladder. It seems that seven years before he had had a stone crushed, and ever since had had to use a catheter. This he kept in his pocket and lubricated by a rough and ready method in his mouth. He came into hospital as a private patient, and I found a stone on sounding him under chloroform with a lithotrite. The stone was immediately on opening the stomach I could make nothing of it, and had to do œsophagotomy after all. The depth of its site offered no obstacle to the easy reach and removal of the plate by this route. The wounds of the stomach and abdomen healed quite simply, and that of the œsophagus granulated and healed without untoward incident. Two years later, when I happened to meet the patient, he said he had had no further trouble, and was then quite well.

Liverpool.

OBSERVATIONS ON THE FUNGI FOUND IN TROPICAL BRONCHOMYCOSIS.

BY ALDO CASTELLANI, M.D. FLORENCE,
DIRECTOR, CLINIC FOR TROPICAL DISEASES, COLOMBO.

IN previous publications I have called attention to the great frequency in the tropics of bronchial affections very probably due to hyphomycetes. I have also given a clinical description of such conditions (so-called tea-factory cough, copra cough, &c.) which at times closely resemble phthisis.[1] In this paper I propose to give briefly the results of the further investigation on the fungi which I have so far isolated. The technique has been given in other papers; a precaution which is absolutely necessary to take in such

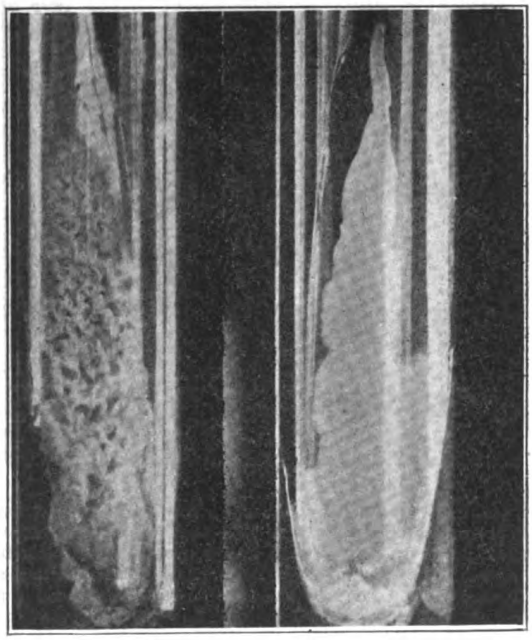
[1] Castellani: Philippine Journal or Science, 1910. Castellani: Centralblatt für Bakteriologie, 1911.

researches is to collect the expectoration in sterile bottles or Petri dishes and to inoculate the various media immediately after collection. The fungi I have so far found in cases of tropical bronchomycosis may be classified as follows. 1. Those belonging to the genus Endomyces. 2. Those belonging to the genus Saccharomyces. 3. Those belonging to the genera Aspergillus and Penicillium. 4. Those belonging to the genera Streptothrix and Actinomyces. 5. Non-determined fungi.

Fungi of the genus Endomyces.—These are in Ceylon the commonest fungi found in bronchomycosis; for the type of the disease caused by them I suggested the term "broncho-oidiosis," or "broncho-endomycosis." Microscopically in the sputum round or oval shape yeast-like cells are seen, and at times segments of mycelium. They are easily grown on the various slightly acid sugar media and also—though less abundant—on ordinary slightly alkaline agar. On sugar agars they give rise to roundish, thick, creamy-white colonies which soon coalesce. They are all *Gram-positive*, do not liquefy gelatin (21 days). In contrast to the usual endomyces albicans none of them liquefies gelatin and none of them (except three) coagulate milk. I have so far isolated 24 strains; 13 are absolutely identical to each other, and correspond to the type of endomyces which I called Endomyces tropicalis (Oidium tropicale) (see Figures). The

FIG. 1.

A B



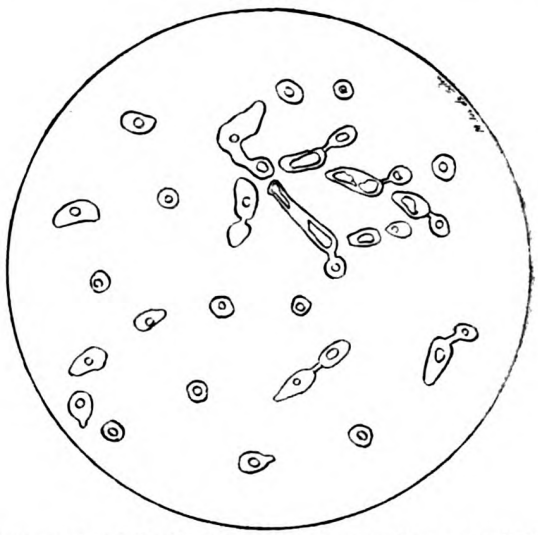
Non-determined fungus; glucose-agar culture. Endomyces tropicalis; maltose-agar culture.

remaining 11 differ from Endomyces tropicalis and differ also among one another; in fact, they are 11 different species. I at first divided these species into two groups—those affecting milk and those not affecting this medium; for the first group I proposed the term "Endomyces pseudotropicalis" and for the second "Endomyces paratropicalis." This nomenclature, however, is not correct, as the same term indicates several different species. I have therefore in this paper retained the term "Endomyces pseudotropicalis" for one species; paratropicalis for another; and I have given a name to each of the nine remaining species (see table).

Fungi of the genus Saccharomyces.—Saccharomyces were isolated from the expectoration of two cases; both strains of saccharomyces are identical and correspond to the type which I have called saccharomyces krusei. They are easily grown on acid as well as ordinary media. They are *Gram-positive*. The culture characters of saccharomyces krusei will be found in the table. Recently I have noticed that after repeated subcultures some mycelium may be observed; it is therefore probable that this fungus will have to be removed from the genus saccharomyces.

Fungi of the genera Actinomyces and Streptothrix.—In two cases of bronchomycosis dark or dark greenish actinomytic-like granules were present. On microscopical examination long, very thin mycelial filaments were seen; they were *Gram-positive* in both cases and acid-fast in one. Attempts at

FIG. 2.

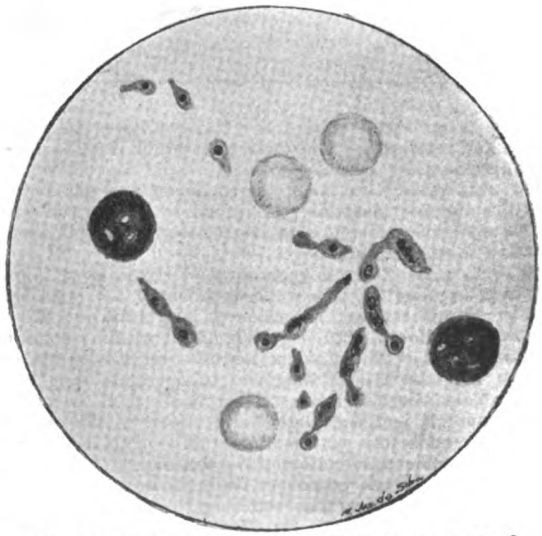


Endomyces tropicalis; fresh preparation from a maltose-agar culture.

cultivation failed. In three cases streptothrix-like fungi of larger dimensions were grown showing different appearances in cultures.

Fungi of the genera Aspergillus and Penicillium.—In a case of chronic bronchitis in an old Singhalese man the expectoration, which was muco-purulent, presented darkish granules containing some mycelial threads. From these granules a fungus was grown identical or very similar to Aspergillus

FIG. 3.



Endomyces tropicalis in the expectoration of a severe case of bronchomycosis. (From a preparation stained with methylene blue.)

fumigatus (Fresenius). In another case with the same type of expectoration a fungus presenting penicillium-like fructifications was isolated. In a third case with muco-purulent expectoration, but without dark granules, an aspergillus producing white or whitish-greenish colonies was grown.

Abbreviations used in the table:—A, Production of acid. B, The growth and medium surrounding slightly brown. G, Production of gas. O, Negative result—viz., neither acid nor clot in milk, neither acid nor gas in sugar media, or non-liquefaction of gelatin or serum, as the case may be.

* Clear, thin pellicle. † Clear, good bottom growth, no pellicle. ‡ Practically no growth. § If any change, slightly alkaline. ‖ Alkaline in seven days. ¶ Trace only. ** Decolourised; clot in five days. †† Alkaline, then peptonisation. ‡‡ Non-liquefied, three weeks.

Non-determined fungi.—In several cases fungi were isolated which so far I have been unable to determine. One gives rise to beautiful pink-coloured colonies. Another found in two cases somewhat resembles an endomyces; it grows very rapidly on all the usual media, and especially so on glucose agar. The appearance of the growth is practically the same in all the various sugar agars; the growth is abundant, of a yellowish colour, the surface convoluted or crinkled. (See Fig. 1, A.) Fresh preparations from the cultures show a large amount of long, regular, septate mycelial threads 2–3 microns in breadth and numerous free roundish spores.

Conclusions.—The fungi so far observed in Ceylon in cases of bronchomycosis are 12 different species of endomyces, the commonest being Endomyces tropicalis, Saccharomyces krusei, various strains of Actinomyces and Streptothrix, fungi of the genera Aspergillus and Penicillium, and several other fungi which so far I have not determined. As regards the pathogenicity of the fungi found it would seem from some researches I have carried out that the pathogenicity of Endomyces tropicalis and of the fungi of the genera Aspergillus, Penicillium, Streptothrix, and Actinomyces is practically certain.

Colombo, Ceylon.

THEORY AND PRACTICE IN THE TREATMENT OF GLAUCOMA.

BY J. HERBERT PARSONS, D.SC. LOND., F.R.C.S. ENG.,
OPHTHALMIC SURGEON, UNIVERSITY COLLEGE HOSPITAL; SURGEON, ROYAL LONDON (MOORFIELDS) OPHTHALMIC HOSPITAL.

IN 1856 Albrecht von Graefe, then a young teacher in the Berlin University, only 28 years old, introduced the operation of iridectomy for the relief of glaucoma. "For thousands of years hosts of sufferers from glaucoma sank without relief into the night of blindness; by the introduction of iridectomy A. von Graefe pointed out the way whereby their vision might be retained. Had he accomplished nothing more he would by this one act have merited the crown of immortality and a place in the little band of heroes who are the benefactors, not of a nation alone, but of all mankind." These eloquent words, written more than 30 years ago by Professor Schmidt-Rimpler, would be endorsed by every ophthalmologist to-day. None the less, the battle is not yet won, for to-day, too, thousands of sufferers from glaucoma drift into the night of darkness, not, it is true, wholly unrelieved, but often, unhappily, with a relief which is but a postponement of the inevitable end.

Glaucoma, in the broad use of the term, is the condition of pathologically increased intraocular tension. Two great groups of cases may be distinguished: those in which increased tension is the result of inflammatory changes occurring in the ciliary body, and those in which there is no evidence of primary inflammatory change in any part of the eye. It is well to reserve the term glaucoma, in its narrower sense, for the latter group. The pathology of these cases is quite different, and it is amongst them that iridectomy and cognate operations are most clearly indicated.

This group again is broadly subdivided into two subgroups—primary acute and chronic glaucoma. The former is characterised by sudden onset, great increase of tension, intense vascular congestion, and severe pain; the latter by insidious onset, slow progress, intermittent and often scarcely appreciable increase of tension, absence of marked vascular congestion, and freedom from pain. In the former the vision fails very rapidly; in the latter very slowly. The difference between the two classes is so marked that they might almost be considered different diseases. They have this point of contact, however, in that the chronic cases are subject to exacerbations in which the tension is suddenly raised and the case assumes all the characteristics of a primary acute glaucoma. Primary acute glaucoma is remarkably amenable to operative treatment by iridectomy. The effect is little short of magical; tension and pain are relieved immediately, and if the operation is performed sufficiently early vision is rapidly restored. In chronic glaucoma, on the other hand, iridectomy often fails to stay the progress of the disease. It is by the brilliant results of iridectomy in primary acute glaucoma that von Graefe is still held to merit that crown of immortality which he wears as the benefactor of mankind.

Without the wish to dim the lustre of a single jewel in von Graefe's crown it should be salutary to human intellectual arrogance to note that in the discovery of the cure of primary acute glaucoma by iridectomy theory and practice did not march hand in hand. Von Graefe, with that extraordinary clinical insight which distinguished him more than any other ophthalmologist of the day, with the exception of Mackenzie, had noticed the diminution of intraocular tension following iridectomy in cases of partial anterior staphyloma, corneal ulcer, and so on. He was of opinion that experimental researches on animals supported the view that excision of a broad piece of iris permanently diminished the tension of even the normal eye. Subsequent experiments by more delicate methods do not support this view, and it must be conceded that iridectomy for glaucoma was founded upon deductions from false premises. So notable an example may well instil caution in the acceptance of even the most plausible theories, particularly in biological questions, the complexities of which preclude the accuracy characteristic of physical and mathematical problems. Rather as seekers after truth, then, than as captious critics, let us consider the current theories of intraocular tension, normal and

pathological, in their bearing upon the treatment of chronic glaucoma.

The generally received theory of the normal intraocular pressure, which amounts to about 25 mm. of mercury above the surrounding atmospheric pressure, is as follows. In order that the tension of the eye may be maintained at this raised pressure work must be done, and it is evident that the source of energy must be the blood pressure. This deduction is proved true by the fact that in experiments on animals the intraocular pressure follows passively every change in the general blood pressure. The walls of the globe are kept stretched by the fluid constituent of the contents, which fills the anterior and posterior chambers and permeates the vitreous. This fluid is comparable to the lymph which bathes the tissues in other parts of the body. The generally received view is that it *is* the lymph of the eye. In other parts of the body the chief function of the lymph is to carry food material to the tissue cells, and to carry away the effete products of the cell metabolism. It has a further function of keeping up the normal tissue tension. Both these functions are of unusual importance in the case of the eye. Owing to the nutritional function of the lymph it is not sufficient that the internal pressure should be kept up by stagnant fluid. Owing to the necessity of keeping the pressure constant within the limits of very small variations the amount of fluid must be similarly nearly constant. The lymph is therefore being constantly renewed and as constantly equally removed.

The physical conditions of the formation of lymph in other parts of the body are consistent with its production by a process of filtration out of the capillaries; the amount poured out and its chemical composition are dependent upon the difference of pressure on the two sides of the filtering membrane—i.e., the capillary wall. The difference of pressure is less in the eye than elsewhere; hence the amount of lymph secreted in a given time is small and its chemical composition differs materially from that of lymph elsewhere. As regards the rate of production, it probably takes nearly an hour for the aqueous in the anterior chamber to be renewed; as regards its composition, the large moleculed proteids of the blood plasma are kept back and the lymph is little more than a saline transudate. Experiments show that the ciliary body is specially differentiated for the production of the lymph which nourishes the vitreous body and lens and on which the intraocular tension depends. The other structures of the eye produce only sufficient lymph for their own nutritional and tissue tension requirements.

The removal of lymph from the eye is the function of the canal of Schlemm, with the exception of a very small portion which passes back through the vitreous and is removed by the perivascular lymph channels of the central vessels of the retina.

Such, in brief, is the most widely accepted view of the normal intraocular tension. Upon this theory is built the retention theory of glaucoma—viz., that the increased tension of glaucoma is caused by the retention of an excess of lymph within the eye. Owing to obstruction at the angle of the anterior chamber the path of the fluid from the anterior chamber to the canal of Schlemm is blocked and the tension of the eye rises. The explanation of the efficacy of iridectomy is that the operation opens up the filtration angle and thus restores communication with the canal of Schlemm.[1] Iridectomy in chronic glaucoma is held to fail because the obstruction at the filtration angle is due to firm fibrous adhesion of the root of the iris to the corneo-sclera and the operation fails to restore permeability of these tissues. The aim, therefore, of most surgeons who have attempted to find out a better way has been to establish a permeable path for the fluid into the subconjunctival tissues, where absorption into the blood stream can easily occur.

Not infrequently the operation of iridectomy for glaucoma has been attended by the incarceration of a small portion of the iris in one angle of the wound. In such cases the scar is weak in this situation and subsequently bulges, so that a so-called cystoid cicatrix forms. Although a weak scar of this nature has several grave disadvantages and dangers, it has been found that the effect of the operation on the progress of the glaucoma has been much better than when an apparently more perfect surgical result is obtained. This effect has been so striking that in spite of the dangers of late infection, sympathetic ophthalmia, and so on, a deliberate effort has been made to produce a cystoid cicatrix, as in Lieutenant-Colonel H. Herbert's earlier work on the operative treatment of glaucoma in Bombay. The efficacy of the cystoid cicatrix is attributed to the weakening of the ocular wall at this spot and the possibility of permeation of the loose cicatricial tissue by the intraocular fluid.

In other cases the iridectomy wound has not healed firmly, although no incarceration of iris occurred. The subconjunctival tissue over the wound has been swollen and œdematous and has remained in this condition for an indefinite period. Such cases have also done unexpectedly well from the point of view of the relief of glaucomatous symptoms. The explanation again has been that the weak scar permitted the permeation of the intraocular fluid, and such scars have been termed "filtering cicatrices."

In this case again the effect has been so striking as to have appealed very strongly to surgeons of wide experience, so that over and over again attempts have been made to elaborate some method of ensuring the formation of a filtering cicatrix in this operation. Such are the "small wedge operation" of Lieutenant-Colonel Herbert and the modified iridectomy operation of Lagrange. Others have relinquished the iridectomy and aimed direct at the development of a filtering cicatrix without adventitious aid. Such are the trephine operation of Major R. H. Elliott and the "small flap operation" of Lieutenant-Colonel Herbert.

Now, these operations have given satisfaction in direct proportion to their success in producing the object aimed at—viz., the provision of a channel permeable to the intraocular fluid. When that object has been attained the ameliorative effect upon the progress of the disease has also followed. Of course, in such cases there is great danger of reasoning in a circle and attributing success or failure to the wrong cause. But so far as they go they support the view that the establishment of a filtering cicatrix is a cure for chronic glaucoma, or, at any rate, as much a cure as iridectomy is for primary acute glaucoma.

Here, however, the antinomian spirit—that spirit, be it remembered, which is responsible for so much of the advance of science—steps in and denies *in toto* the efficacy of the filtering cicatrix on theoretical grounds. "The theory of 'filtering cicatrices' rests on the assumption that the aqueous outflow is a filtration. ..... Now, the bases of the volumetric and of the circulatory conceptions of the intraocular pressure are as diametrically opposed as the two poles, and, therefore, while admittedly the theory of 'filtering cicatrices' is perfectly logical with the former premises, it is equally illogical with the latter."[2] What, then, is the "circulatory conception" of the intraocular pressure? It is that: "1. The intraocular pressure is vascular in origin and nature, and stands and varies with intraocular venous pressure. 2. The intraocular pressure is influenced directly and absolutely by a rise in general venous pressure, but only relatively by increase in arterial pressure. 3. The intraocular volume is a fixed quantity. 4. The corneo-scleral envelope represents a rigid case."[3] It will be seen that the primary assumption is that the walls of the globe form a rigid case like the skull, and that, therefore, the whole of Dr. Leonard Hill's work on the cerebral circulation can be applied directly to the intraocular circulation.

Dr. Thomson Henderson's arguments in favour of the view that the walls of the eye are rigid consist chiefly in criticisms of my own writings.[4] That I should have been guilty of the common error of using the word "elasticity" in the colloquial and not in the strictly accurate scientific manner is of little moment. Moreover, it is easy by separating phrases from their context to gather together apparent paradoxes. I have stated that "the globe of the eye is practically rigid," and for slight variations of intraocular pressure the statement is undoubtedly true, and is consonant with the statement that "the stretching under normal physiological pressure is minimal." I do not regard it as

[1] It is necessary to be very precise in one's language on this point. Dr. Thomson Henderson's criticism of my remark that the object of the peripheral incision in iridectomy for glaucoma, as well as the aim of sclerotomy, is to open up the filtration angle and canal of Schlemm, is that "such procedure, if successful, would merely result in phlebotomy, with certainly most undesirable consequences." (Thomson Henderson, Glaucoma, London, Edward Arnold, 1910, p. 202.)

[3] Loc. cit., p. 89.

[4] Parsons: The Pathology of the Eye, vol. iii. London: Hodder and Stoughton.

"flat contradiction" to say that "unlike the cranium, however, the eyeball is not a rigid case," and that the stretching is "quite an appreciable amount," even when the intraocular pressure is raised from 19 mm. to 70 mm. Hg. The last statement is based upon reliable experimental observations by Koster. Dr. Henderson brings forward no evidence whatever to controvert these statements, and we must therefore conclude that, though within the range of physiological pressures, the walls of the globe may be regarded as practically a rigid case, beyond that range deformation occurs which must be taken into account if accurate deductions are to be made.

So far then as variations within the limited range of physiological pressures are concerned Dr. Henderson's working model of the circulatory mechanism of the intraocular pressure has exactly the same value that a good diagram has and no more. Those who have had experience in biological experiments will appreciate the dangers of mechanical working models. They have their use in illustrating proved facts; it is unwise to misuse them to prove disputed points. Within the narrow range of pressures in which the eyeball may be regarded as rigid the general application of Dr. Hill's researches may be freely admitted. Even they, however, should not be pressed too far. To take a simple example, his experiments tend to prove that vaso-motor changes cannot occur within the cranium. Delicate as were the experiments they appear to me to be far too coarse to prove such a point. As the late Professor Michael Foster said of experiments on cerebral localisation, "they are like playing the piano with a broomstick." Now there is plenty of evidence, clinical and experimental, to prove that vaso-motor changes occur in the retinal vessels within the normal range of intraocular pressures, yet Dr. Hill's experimental observations are equally potent in their allotted sphere. Under the conditions named the general features of the intraocular pressure are doubtless the same as those of the intracranial pressure, but only direct experiments on the eye can demonstrate what modifications in detail may be present. Beyond the given range one fact alone suffices to show that the conditions are quite dissimilar. When the animal is killed the intracranial pressure promptly sinks to zero; not so, however, the intra-ocular pressure, which, under these circumstances or when the eye is excised, only reaches zero after a prolonged period—in fact, after fluid has filtered out.

With regard to the production of aqueous Dr. Henderson adopts the secretory view in common with many who hold what he calls the "volumetric" theory. They, however, do not go so far as to say that "mechanical filtration is impossible." It is difficult to understand what he means when he says that "there can be no difference in hydrostatic level on either side of the filtering membrane." The filtering membrane is the capillary wall, and whatever may be the reason why the fluid passes into the posterior chamber and not into the suprachoroidal space, it is certain that the intracapillary pressure is greater than the extracapillary—i.e., the intraocular—pressure, and therefore the filtration factor must come into play. Resorption of aqueous is regarded as a pure diffusion into the veins, particularly the canal of Schlemm and the veins of the iris. Dr. Henderson believes that many of the ciliary vessels which have been described as arteries are really veins.

On the assumption that even under pathological conditions of increased tension the walls of the eye are still a rigid case, the explanation of glaucoma is held to be due, not to a "retention of intraocular volume," but to a "retention of intraocular pressure." The language is cryptic, but taken with the context the meaning is clear. On blocking the venous exits—canal of Schlemm by sclerosis of the ligamentum pectinatum and anterior ciliary veins by peripheral anterior synechia—the elastic blood-vessels are transformed into a rigid system of tubes. In such a system the outflow pressure is always higher than in a similar system of elastic tubes; hence in glaucoma the lowest circulatory pressure is that in a rigid system, and therefore the intraocular pressure is maintained at a correspondingly high level. The observations on sclerosis of the ligamentum pectinatum agree with those of other pathologists. Resorption of aqueous is reduced to the area of the iris veins. The aqueous is therefore not entirely cut off from the veins; the aqueous volume is displaced by increase of total vascular volume, so that the anterior chamber becomes shallow. The explanations of the dilatation of the pupil, haziness of the cornea, occlusion of the angle of the anterior chamber, and so on, are very ingenious, but are open to criticism in many respects.

The efficacy of iridectomy in glaucoma is attributed to the free opening up of access to the iris veins. This is facilitated by the fact that wounds of the iris do not undergo cicatrisation like other wounds, and consequently the aqueous is brought into contact with the vessels of the iris throughout the length of both edges of the coloboma.

That the hydrostatic principles underlying Dr. Henderson's theory have to be taken into account needs no proof, and he has done great service in forcing them vigorously upon the attention of ophthalmologists. That there are conditions, normal and pathological, in which they play a preponderant rôle may equally be admitted. That they alone can be held to account for the pathogenesis of glaucoma is a view unlikely to commend itself to most pathologists, who will still hold that the major variations in the intraocular pressure are brought about by actual variations in the fluid contents of the globe. Further research will probably show that the two theories are not so inconsistent as Dr. Henderson would have us believe.

There yet remains an operation for chronic glaucoma which has not been considered—cyclodialysis. By this means Dr. Heine attempted to provide an exit of the intraocular fluid by way of the suprachoroidal space. It appears to be satisfactory so long as the artificial detachment of the ciliary body from the sclerotic persists, but fibrous reunion occurs and the intraocular tension again rises. According to Dr. Henderson there is normally free passage of aqueous from the anterior chamber into the suprachoroidal space; his evidence, however, is not convincing. Dr. A. Freeland Fergus combines the operation of trephining with cyclodialysis.

In conclusion, if the criticisms put forward here are just, the formation of a filtering cicatrix holds out the best hope of alleviating chronic glaucoma.

Queen Anne-street, W.

LYMPHATIC VARICOCELE.

BY FRANK COLE MADDEN, M.D. MELB., F.R.C.S. ENG.,

PROFESSOR OF SURGERY, EGYPTIAN GOVERNMENT SCHOOL OF MEDICINE; SENIOR SURGEON, KASR-EL-AINY HOSPITAL, CAIRO.

WE have recently operated on three cases presenting the usual clinical signs and symptoms of varicocele, but have found that the swelling was due to the presence of tortuous coils of very thin-walled, dilated lymphatics in the substance of the spermatic cord. This condition is, in all probability, a manifestation of filariasis, though we have not succeeded in finding filarial embryos in the blood—a fact that proves nothing of itself, but it would have been a source of satisfaction to have had confirmation of our thesis.

Our attention was first drawn to the condition I wish to describe whilst operating on a case which had been operated on a few months before for varicocele. A very temporary relief had followed the first operation, but the swelling had returned in a more severe degree shortly afterwards. At the second operation we found that the varicocele had been completely cured—if, indeed, it had ever existed; but we were surprised to find masses of thin, translucent, dilated lymphatics extending along the whole length of the cord. The affected lymphatics were excised, and so far there has been no recurrence, though, if the enlargement is due to a compensatory dilatation to provide a collateral circulation around a blocked lymphatic trunk in the pelvis or lower abdomen, the permanency of the cure is very uncertain.

The following case brings out the main points of the condition and its liability to recur, and may be taken as a type.

The patient, aged 20, was admitted to Kasr-el-Ainy Hospital on Sept. 10th, 1911, complaining of pain in the right side of the scrotum. He had been suffering from this pain for the last five years, especially after prolonged standing or walking, and it was gradually increasing in severity. There was no history of fever or any other previous disease, either in the scrotum or elsewhere, and the urine was clear, with specific gravity 1022, acid in reaction, and entirely

free of albumin, sugar, or other abnormal constituent. No filarial embryos were found in his blood. He had been operated on in February, 1911, by my colleague, Dr. Aly Ibrahim, for hernia and varicocele, but the veins were not enlarged, and running with the hernial sac was a "cystic enlargement of the cord extending as far as the external ring. The thickening consisted of separate cystic enlargements, each of which was constricted at certain points, as though valves were present in the course of the dilated vessels." The true nature of the enlargement was not then recognised, but the cystic dilatations were excised between ligatures, and the radical operation for hernia was completed.

Very soon after this operation the swelling of the cord returned, and this was thought to be a thrombosis of the veins of the cord which would probably gradually subside. The swelling, however, remained stationary, and on readmission to hospital the enlargement very closely resembled varicocele, even giving a faint impulse on coughing, and diminishing in size on lying down and refilling on standing.

A second operation was performed. Under stovaine anæsthesia the old scar was resected, and the entire length of the cord was exposed from the external ring to the testis. The swelling was then seen to consist of a large number of coils of dilated lymphatics having a sacculated appearance, like sausage-skins of very small calibre, and distended with clear lymph. These coils completely surrounded the other constituents of the cord and extended into the abdomen. The veins were not affected. The mass of lymphatics was removed between ligatures above and below, and the operation was completed as though the mass had consisted of dilated veins. The scrotum was stitched up vertically in its upper part and transversely below to shorten the pendulous scrotum. After removal it was seen that the lymphatics formed long coiled tubes, held lightly together at some points by loose connective tissue. The subsequent history of the case was uneventful, and the enlargement has not yet returned.

This condition adds yet another to the already lengthy list of possibilities in the scrotum, and if it is a filarial manifestation, which it almost certainly is, it is further of interest on account of its restricted distribution. I do not remember to have read any report of filarial lymphatic dilatation strictly limited to the lymphatics of the spermatic cord, without any implication of the scrotum, either superficial or deep.

I am much indebted to Dr. Abd-el-Fataah, resident surgical officer, for the notes of this case.

Note.—In operating on hernia and varicocele one not infrequently finds thick, white, tenacious masses of coagulated lymph in and around the spermatic cord, very similar to the more organised lymphy tissue which has to be stripped off the cords in the operation for elephantiasis of the scrotum. This is probably due to exudation of lymph from increased lymph pressure in the lymphatics of the cord and surrounding connective tissue, and is not necessarily filarial at all. It is quite different from the condition above described and no appreciable dilatation of lymphatics is present.

Cairo.

SOME OBSERVATIONS ON

THE PREVENTION OF TUBERCULOSIS.

BY J. SIM WALLACE, M.D., D.SC. GLASG., L.D.S.,

DENTAL SURGEON AND LECTURER ON DENTAL SURGERY AND PATHOLOGY TO THE LONDON HOSPITAL.

GENERALLY speaking, the healthy individual is an asset to the community, while the diseased are liable to be a burden. It would, therefore, seem to be to the advantage of the community to *prevent* disease. The treatment of disease is often quite a different matter. Once a disease, such as tuberculosis, effects an entry into the system, not only may the individual be completely incapacitated for work, but *curing* the disease is problematical, even with the aid of lavish expenditure. The extreme tenacity with which disease germs keep hold of their host once they have gained an entrance into it was well brought out in a recent address by Sir Hector Cameron,[1] but this fact is well known, and further reference to it is unnecessary here.

In days gone past the difficulty of expense in treatment was no doubt got over by the victim of such diseases entering an early grave; but it being impossible to countenance such a course of events now, we must consider whether it would not be profitable to direct more attention to prevention. It is particularly necessary to do so because the incubus of taxation for the treatment of tuberculosis and other diseases probably is a fruitful cause of tuberculosis and many other diseases.

There are two principal ways in which tuberculosis may be prevented: (1) The environment of the individual may be kept free, relatively at least, from germs which are liable to cause the disease; (2) the individual may be kept sufficiently healthy to resist the effective entrance of disease germs. That the first method is important, especially in the more infectious diseases, is of course recognised. In the case of tuberculosis it is not so obvious, but that it is so is noticeable when the question is gone into completely.[2] I do not intend, however, to deal with this part of the subject. It is to the possibility of more effectually keeping the body sufficiently fit to be able to resist the tubercle bacilli that I intend to direct attention, because the recommendations about to be made are as yet relatively unknown.

The two chief routes of entry of the tubercle bacilli into the system appear to be *viâ* the alimentary canal and the faucial and pharyngeal tonsils. With regard to entrance *viâ* the alimentary canal, we know that *in a healthy state* entrance in this way is hardly to be expected, and, as a matter of fact, though all people must swallow living tubercle bacilli many times during their life—perhaps, indeed, many times during each day—yet the tubercle bacilli do not by any means always gain effective entrance into the system.

In the past—attention being directed exclusively to the consideration of the nutritive values, the number of "calories," the rapidity of digestion, the assimilability of the food, &c.—no real consideration seems to have been given to a most important, perhaps the most important, principle of dietetics—viz., the principle which claims that the meals should be so arranged that the mouth and alimentary canal shall be left in a hygienic state at the end of each meal.

With regard to the mouth, it may be said that but few could indicate with the slightest degree of accuracy the nature of the foods which tend to leave the mouth in a hygienic state. Yet this is the beginning of the trouble; for if the mouth is, generally speaking, in an unhygienic state after meals—as it, indeed, very generally is—then what chance has the stomach and alimentary canal to be free from injury from the constant swallowing of septic matter, polluted food, or decomposing food remains. Furthermore, if the mouth is left in an unhygienic state, what chance have the teeth of remaining free from caries or the gums from being injured between the teeth by the more or less constant lodgment of fermenting food.

We now know that dental diseases are, in general, neither hereditary nor constitutional, but that they are the result of habitual dietetic error. The dietetic error which brings on dental troubles has little or nothing to do with the question as to whether the food is nutritious or not. The point of importance is whether the food leaves the mouth in a hygienic state at the end of the meal or otherwise. It is not my intention to consider which foods are cleansing to the mouth and teeth and which are not. Here it must simply suffice to say that those physicians who have really considered the subject now recognise that soft milk-soaked foods do not keep the mouth in a hygienic state, and moreover some note the probability that these foods are neither directly nor indirectly conducive to the hygiene of the alimentary canal. Thus, Dr. G. A. Sutherland, when referring to the preventive treatment of tubercular peritonitis, says that "the real risk lies in an unhealthy condition of the alimentary canal which may allow the penetration of the bacilli." He urges the wisdom of a type of diet requiring mastication such as would tend to keep the alimentary canal in a healthy state, and comments on the feeding of children with tubercular tendencies on "a sloppy diet—milk, bread and milk, and pudding." He says: "Experience has shown that this is the worst possible form of treatment."[3]

Further comment on the system of feeding which keeps the mouth and alimentary canal in an unhygienic state is not

[1] The Persistence of Disease Germs in the Human Body, Brit. Med Jour., 1911, vol. i., p. 973.

[2] Newsholme: Prevention of Tuberculosis.

[3] The Treatment of Diseases in Children, p. 110.

necessary. It behoves those who would lend a helping hand in the prevention of tuberculosis to become acquainted with the more recent views on diet from the point of view of oral and alimentary hygiene, lest they may help to continue "the worst possible" system of feeding children.

The other important mode of entry of the tubercle bacilli is via the pharyngeal and faucial tonsils when these are in a diseased state. This is, perhaps, the commonest way in which these micro-organisms enter the system. An interesting investigation of Dr. H. Osborne[4] shows how very constantly diseased lymphatic glands are associated with pathological hypertrophy of the pharyngeal and faucial tonsils. That "infecting organisms may obtain access more readily by way of enlarged tonsils and adenoids than through the healthy nose and throat" can hardly be doubted. It is consequently of great importance in the prevention of tuberculosis that the causes of adenoids and enlarged tonsils should be recognised and combated.

It is not my intention to enter into the question of causation fully; all that I would do at present is to recall the well-known fact that adenoids are more frequent in cold and damp localities, and in a short investigation which I made a few years ago it transpired that of 49 children who were brought up on the open-window principle in all weathers (whether cold and damp or otherwise), 22 of these children developed adenoids to such an extent that they had to be operated on. While, on the other hand, of 69 children of a similar class, who had been brought up with the windows of their bedrooms shut at night, only two cases of adenoids were noted.

It may here be observed that the liability to catarrhal troubles of the naso-pharynx, or at least to adenoids, resulting from a strict adherence to the open-window system of ventilation in cold and damp nights is generally admitted now by those few laryngologists who have been persuaded to look into this subject. And it might be well also to say that those medical men who still advocate the open window at night, in all weathers and under all circumstances, should bring forward statistics to justify their recommendations. At present, as regards adenoids, there do not seem to be any statistics whatever to justify the attitude which they take up; and, moreover, the fact that during recent years pneumonia has come to account for a greater number of deaths than any other disease whatsoever indicates most emphatically that care should be exercised before recommending or enforcing a procedure having no statistical evidence to support it, which is contra-indicated both by instinct and by reason.

But recognising that there is difference of opinion on this important point, it is evident that we must have this question as to the causation of adenoids definitely settled. It is a very easy investigation to those who have the opportunity of seeing numerous school children. It does not require a laboratory or expensive equipment, and yet this simple investigation will, I have no doubt, prove to the medical world—as it has done to those who have already looked into the subject—that adenoids are easily preventable in nine cases out of ten. There are, of course, other cogent reasons for insisting on the elucidation of the causation of adenoids. The sequelæ are often disastrous when the patient lives; moreover, the operation for the removal is not always productive of very satisfactory results as regards breathing, while the risk of death during or immediately after the operation is fairly well recognised.

Now, if we recognise the fact that there has been a general diminution in tuberculosis due to cheap food, better housing, smaller families, and improved sanitation, we must also recognise that increased taxation, for the sake of State *treatment*, leaves less money for the individual to spend on food, clothing, medical attendance, and proper housing accommodation.

Only a few hundreds of those treated in sanatoriums are physically rehabilitated so that they become useful members of the community; on the other hand, there are tens of thousands, nay, several millions, who can ill afford the money required by the tax-gatherers. There is, indeed, but a mere handful the taxation of whom would be beneficial for themselves and the community. Nor is it evident that, even though taxation were limited to the rich, the tax would not ultimately really fall upon those who could not afford it without denying themselves the comforts which are conducive to health.

It must not be thought, moreover, that it is only the very poor who would feel the pinch. Here, for example, are some statistics culled from Mr. Culpin's report on overcrowding and child development:—

Boys from 15 to 18 years of age living in—	4-roomed houses weigh on the average	64·3 lb.
	3- " " " " "	60·6 "
	2- " " " " "	56·1 "
	1- " " " " "	52·6 "

The average difference in weight of boys living in 1-, 2-, 3-, and 4-roomed houses is roughly 4 lb. for each additional room, and the height of such boys is correspondingly more for each additional room. We find that a boy living in a one-room tenement is 4·7 in. shorter and 11·7 lb. lighter than one from a four-roomed house. It is evident, therefore, that it is not only those who live in a one-, two-, or even three-roomed house who will suffer from increased taxation for the treatment of disease. Statistics similarly show that tuberculosis is more prevalent the smaller and more overcrowded the house.

The most rational, economical, and just system is for the State to do what seems necessary to prevent disease; everyone would participate in the benefit. The expense of the treatment of the individual should fall on the individual or those responsible. Of course, as a matter of charity the individual sufferer would in the future, as in the past, be liberally aided by those who voluntarily contribute for the relief of suffering, even though such suffering be the result of his own negligence or misdeeds.

Another aspect of the subject demands the most careful consideration. It would appear that there was a marked decrease in the mortality from phthisis from 1850 to 1894, since which time it has ceased to decrease so rapidly, or, to put it in Professor Karl Pearson's words:—

> The death-rate from phthisis during our period of supposed greatest knowledge, and during the time of our most active campaign against tuberculosis, has ceased to be reduced at the old rate. There is actually a slackening in the rate of fall. Increased knowledge and increased medical activity have not been associated with that acceleration in the fall of the phthisical death-rate which we should have anticipated.

Professor Pearson's *statistics* must be considered, and the sooner the better. They seem to me to emphasise the points which I have drawn attention to at the beginning of this paper. We need not be disheartened by his *inferences*; for by overlooking the fact that age and environment bring about a certain immunity to tuberculosis he has obviously been led into error.

Professor Pearson's charts, however, showing the rapid decline in mortality until recent years are worthy of consideration. To many they will be startling, but there is, indeed, nothing very surprising in them to those who recognise that the welfare of children has been most seriously compromised by the current unhygienic system of feeding them, together with the unhygienic state of the mouth and alimentary canal which has resulted therefrom. Still less will his statistics cause surprise among those who recognise also that adenoids and diseased tonsils are common roads of entrance to the tubercle bacilli.

Let us, however, leave out of account considerations with regard to the causation of adenoids, upon which subject there is still marked difference of opinion. Let us consider solely the fact that about 40 per cent. of children suffer from "extensive and injurious decay of teeth,"[5] and that dental caries "must be considered as an outward and visible sign of methods of living which produce other and still greater harm."[6]

Surely, when we consider such facts it is obvious that if the medical profession would help in the costless campaign against such methods of living, which cause such disastrous results, it would confer an even greater benefaction on humanity than it has as yet been able to do, for if instead of advocating the "worst possible" it were to introduce the hygienic—the obviously physiologically correct system—an untold amount of suffering and disease would assuredly be prevented.

A NEW METHOD OF COUNTING LEUCOCYTES.

BY R. A. P. HILL, M.B. CANTAB., D.P.H.

THE advantage of the method here described is that a total and differential count may be done simultaneously, the whole process taking about ten minutes or less. The only apparatus needed besides the usual Thoma pipette and slide is a small cylindrical tube graduated and corked. The tube of a Haldane's hæmoglobinometer cut down to the level of the 120 mark is very convenient. Liquor potassæ will clean it after use. The diluent must be made up at the time. Its composition is: Distilled water, 12 parts; acetone, 3 parts; methyl alcohol, 1 part; and Wright's modification of Leishman's stain, 4 parts.

This reagent is used as the diluent for the blood in any dilutions from 1 in 200 to 1 in 10. The red cells become almost invisible, the leucocytes stain just as they do in a film, and can be distinguished without the least difficulty. A dilution of 1 in 100 will give some 80 cells on the big square of a Thoma-Zappert slide, which is quite a large enough number to give an accurate total count, and there is no difficulty in finding 300 cells in other parts of the field for the differential. In marked leucopenia a 1 in 10 dilution enables one to find as many cells as are needed in a few minutes. There is no overstaining or precipitation in the course of two hours; there is no difficulty arising from unequal distribution or distortion or bad staining, such as one meets with in film preparations, especially if made on a slide, and in many cases one glance is enough to reveal the condition—as, for instance, a marked eosinophilia, or excess of lymphocytes, large mononuclears or polymorphic cells.

The stain will keep for several hours if corked, but it is best to prepare just enough for use each time; that is the purpose of the small cylinder. With a hæmoglobinometer tube 24 divisions of water and the rest in proportion is enough for a 1 in 100 pipette if it can reach to the bottom.

Besides the absolute cleanliness and the purity of reagents necessary for all blood work, three precautions must be observed.

1. *The Wright's stain must be filtered. It is best to do this at the time of making it up.* I grind up a tabloid with 10 c.c. of methyl alcohol and filter. About 3 c.c. are lost by evaporation, so I grind up the residue in the mortar with another 5 or 6 c.c. of alcohol and pour it through the filter till 10 c.c. have come through. I keep the same filter paper for months, so that the solution is saturated. If now 2½ c.c. of methyl alcohol are added direct to the filtered stain there is no need to add it separately in making up the diluent fluid; instead one can add 5 parts of this diluted stain after the acetone. This dilution in no way impairs its utility for staining films, but is in some ways an advantage, as one need not trouble to prevent evaporation, since it does not so easily precipitate. If well corked it appears to keep for a long time.

2. *The mixture must be very well shaken.* If this is not done a froth will form in the bulb of the pipette.

3. The various operations of mixing and putting the drop on the slide must be done with promptness; especially must the drop be covered as soon as possible, as the cells settle quickly and the acetone evaporates readily. For this reason I imagine a counting chamber with an air inlet would not be very suitable.

If these precautions are observed the method is both simple and satisfactory. The cells are best seen with the flat mirror and when the condenser is screwed down and the diaphragm half closed. A thin cover-slip and high magnification may be used.

I have tried to preserve the red cells for counting also with various modifications of reagent and method, but so far without any success. As the acetone evaporates they become visible, but this is not till after a long while, and they appear to be in clumps. All the methods I have yet tried have resulted either in clusters of red cells or diffuse staining of the leucocytes. It would obviously be a great advantage if a red, white, and differential count could all be done in one operation.

This method was suggested to me by the work of R. Dunger, who described a similar method of demonstrating eosinophilia, by using eosin dissolved in dilute acetone as a diluent.[1]

Union Medical College, Peking, China.

A CASE OF CEREBRAL MALARIA: RECOVERY AFTER 48 HOURS' UNCONSCIOUSNESS.

BY W. THOROLD QUAIFE, M.B., CH.M. SYD., D.T.M. & HY. CAMB.

THE patient was a native of Ysabel Island, aged 18, strong, healthy, and well-nourished, and was employed on a small sailing vessel. On August 25th, 1911, he worked in his usual health during the day. He helped to heave up the anchor at 11 P.M. At 12 midnight he suddenly fell down "with violent convulsions" and deep unconsciousness. He soon became quiet and remained so all night.

August 26th, 10 A.M: Patient was brought to me. Deep coma present; corneal reflex absent; pupils moderately dilated, equal, reacting slowly to light. Temperature 101° F.; pulse 160, volume and tension medium; respiration rapid and stertorous. The whole muscular system was completely relaxed. No physical signs noted in chest. Abdomen retracted, soft; spleen palpable 2 inches below costal margin, with firm, thick, rounded border. Liver just palpable, soft. No jaundice present. 10.15 A.M.: Quinine bihydrochloride, gr. 30, dissolved in 6 oz. water, given by the rectum. Distinct resistance to movement in arms felt. Fresh films of blood taken now showed a few half-grown pigmented malignant tertian malaria parasites. 11 A.M.: Occasional convulsive movements of arms and hands and facial muscles noted. Later corneal reflexes appeared, and marked resistance to passive movements of arms. Lower extremities soft and flaccid throughout. 3 P.M.: Pulse 150, softer; temperature 101°; respiration more laboured, all the accessory muscles of respiration being called into play. Corneal reflex just present. Quinine bihydrochloride, gr. 30, given by the rectum. 10 P.M.: Respiration rather easier; pulse 140, very feeble; temperature 101°. Corneal reflex present. Continuous movements of arms, hands, and facial muscles now very marked. Quinine bihydrochloride, gr. 30, given by rectum.

August 27th, 6 A.M.: Temperature 100°; respiration quite easy; pulse 116, tension fair, very much improved. The patient was unconscious, but all the reflexes were present except in the lower limbs. He turned his head in the direction of any loud noise. The lower extremities were flaccid and there was no resistance to passive movement. He resisted passive movement to the arms and head. There was now present slight icterus, to be noted in the sclerotics. He immediately rejected any fluid put into the mouth, with thin pus from a rather marked condition of pyorrhœa alveolaris. Bladder emptied by catheter. Bowels moved under him later in day. 6 P.M.: Condition generally unchanged. Pulse 110, rather improved. Still unconscious. 12 midnight: Much brighter, but still quite dazed. Moved legs with some difficulty. Later he sat up and then lay down on the floor, and passed urine naturally. No quinine was given to-day.

August 28th, 6 A.M.: Pulse 100, good quality. Stupid, and could not understand much that was said to him. Could walk with support though the legs were slightly ataxic. Took and ate biscuits given him, but immediately rejected quinine. Slept most of the day.

August 29th: A little weak but quite sensible and walked quite well. Pulse 90, good; temperature 98°. Quinine bihydrochloride, gr. 15, given in solution by the mouth and retained.

Later the boy made a complete recovery and no complications ensued.

SECTION FOR THE STUDY OF DISEASE IN CHILDREN.

Tuberculous Joint Disease in Children.

A MEETING of this section was held on Dec. 15th, 1911, Dr. G. A. SUTHERLAND, the President, being in the chair.

A discussion on the Treatment of Tuberculous Joint Disease in Children was opened by Mr. A. H. TUBBY, Sir ANTHONY A. BOWLBY, and Dr. A. BUTLER HARRIS.

Mr. A. H. TUBBY'S address, dealing with the "Indications for Surgical Interference in the Treatment of Tuberculous Joint Disease in Children, with Remarks as to the After-Results," will be found at p. 4.

Sir ANTHONY A. BOWLBY, dealing with the "Results Obtainable without Operation," said that tuberculous disease of the joints in children stood in a different position from similar diseases in the adult because of the much greater powers of resistance and repair shown in the tissues affected. He alluded to the pathological processes of tuberculous infection of the bone, pointing out how rapidly and extensively bone might be absorbed in children, and how exceptionally suppuration occurred. Growth of new bone in the child was very rapid, and it was this absorption of tubercular bone and the growth of new bone that enabled the tubercular joints of children to repair themselves so remarkably. The soft parts in the child also had this power of repair denied to the adult. But these powers of repair must depend largely upon the health and nutrition of the child, whence it was imperative to attend to the general health. Good and plentiful food of an easily assimilable nature, in which milk played an important part, was essential. The bowels should be regulated, and iron, cod-liver oil, and malt administered. All possible sources of ill-health should be attended to, especially tonsils, adenoids, and carious teeth. The local treatment of the joint by splints was considered, and a recumbent position for a time, even when a joint of the upper limb was involved, was insisted on. Stress was laid on the importance of open-air life. He thought he had seen tuberculin do good in some cases. The advent of asepsis had completely altered the whole picture of tubercle in joints, for death was more often caused by sepsis than by tubercle. In dealing with abscesses the greatest possible care was necessary both to prevent the joint becoming septic, and not to infect neighbouring tissues with tubercle. His treatment of abscess was aseptic incision and temporary drainage. Even with open and septic sinuses in the larger number of cases the limb could be saved by directing one's efforts to the general health of the child, by doing all that could be done locally, and by vaccines to obtain an aseptic condition. He amputated less and less frequently for even apparently desperate conditions, for he had seen children recover from most extensive emaciation and amyloid disease, with hectic fever, when treated conservatively. In many cases treated early and for a sufficient time he had seen complete restoration of function, and except for a little impairment in bulk of the limb it had been impossible to tell which joint had been involved. He considered that almost all cases taken in the early stages were really curable in the widest sense of the term. In his experience tuberculosis of the lungs or the glands was a very rare complication. Occasionally general tuberculosis occurred. In some cases the disease was multi-articular. In concluding, he gave a very favourable view of the curability of tubercular joint disease in children, expressing his opinion that what was wanted was increased accommodation in hospitals in the country for the treatment of the disease.

Dr. A. BUTLER HARRIS, dealing with the Rôle of Vaccine Therapy, said that the Royal Commission in its final report had published evidence which went to prove that a considerable amount of tuberculosis in childhood was to be ascribed to infection with bacilli of the bovine type, transmitted in meals consisting largely of cow's milk. It was generally recognised, though not sufficiently guarded against, that tubercle bacilli were abundantly present in the milk of cows with tubercular disease of the udder. But bacilli might be present in the milk of tubercular cows showing no evidence of such disease, even when examined post mortem. Amongst working-classes environment as well as food was an important factor, and it must be admitted that a very considerable number of bacilli found in the joints of children gave the human reaction. As far as was known at present, it did not appear to matter much clinically whether, in the joint affections of children, the strain was of human or bovine origin. The same tuberculin appeared to do well in every case, and the opsonic indices came out equally whether one or other strain was used. It mattered, however, in respect to the general hygiene of the child, for the surroundings must be as free from tubercle bacilli as the food. In the diagnosis of tubercular affections of the joints massive injections of the old tuberculin had been abandoned; Calmette's reaction was out of favour with many, and von Pirquet's reaction, although trustworthy as to the diagnosis of tuberculosis in the human subject, could not differentiate the site of a particular lesion. The estimation of a series of tuberculo-opsonic indices was undoubtedly of use in diagnosis. The method of estimating the indices was described. In spite of the objections raised and the liabilities of error the method was of considerable use in diagnosis. Two methods of treatment were discussed: (1) Methods producing auto-inoculation; and (2) administration of tuberculin. Auto-inoculation was feasible only in the method of passive congestion, and in such the dosage could not be regulated, and a steep negative phase might result. The method was practicable only in joints distal from the trunk, and distal joints were clearly less liable to pour an excess of inoculating material into the body than the proximal ones, and it was interesting that ankles and wrists did better than knees and elbows in this method; it was not commended for hips and shoulders. The advantage claimed for this method was that an autogenous vaccine was introduced. This, however, was of little moment, since there was no evidence that one strain of tuberculin was better than another for therapeutic inoculation. The conditions and mode of administration of tuberculin were fully discussed, and the somewhat divergent information as to the value of tuberculin, received in answer to a circular letter sent to 13 hospitals, was presented. It was concluded that tuberculin, given in small doses under conditions of surgical rest, tended to accelerate the rate of recovery. It was generally the practice to administer Koch's T.R. of human origin whether the infection was of the bovine or human strain, and children, on the whole, did better on this than on the bovine strain. It was not necessary to use the opsonic index during the whole course of treatment, provided the case was clinically pursuing a favourable course.

Mr. ROBERT JONES (Liverpool) agreed as to the difference between tubercle in the adult and in the child. In the early stage in children tubercle nearly always ran a benign course if attention was paid to the affected part having absolute rest and the child having good food and good country air. He emphasised the importance of the children being out of doors both day and night. Immobilisation of the joint should be complete, and care should be given to the position of the limb, which he described in detail. He believed children were often taken out of their splints too soon. He described his tests of recovery. He never opened an abscess until it came to the surface, and then only by a very small puncture.

Sir W. WATSON CHEYNE said that he practically never operated now for a tuberculous joint in the child. Tuberculous disease of joints seemed milder than formerly; whether the bacilli were less virulent he did not know. There were diseases which gradually died out. The modern mode of living was certainly more hygienic. He did not think that operation for such disease in children could be put out of mind altogether. In the early stage when the disease was in one focus, removing that focus produced the best results. In the treatment of abscesses he employed antisepsis and asepsis, opened freely, and scraped them out. He always used tuberculin, and thought it did no harm, but he had not yet seen a definite good result which he could attribute to it.

Mr. H. J. GAUVAIN (Alton) ardently supported conservative treatment, but was fully alive to the importance of radical treatment in special circumstances. In his experience in many cases the course of the disease could be foretold, and if it were likely to run a serious course he believed in early operation. Abscesses he invariably aspirated. These children should be treated in the best country air and in specially equipped country hospitals. If all early cases were so treated he believed that there would be about 95 per cent. of recoveries, mostly without deformity.

Mr. J. JACKSON CLARKE raised the point as to the number of cases apparently cured in infancy in which recurrence took place in later life. He had not seen a case ameliorated by tuberculin which had resisted other treatment.

Mr. W. G. SUTCLIFFE (Margate) emphasised the long time these cases required to heal, the average time for a tuberculous knee or hip being four or five years. Hip cases did best if continually kept in bed for many months. He used tuberculin but had seen no definite results from it.

Mr. E. M. CORNER said that if there was an abscess the case would sooner or later come to operation, and he preferred to incise the abscess, wash it out, and employ temporary drainage. With regard to the number of cases that got well without operation he urged the importance of accurate diagnosis. The diagnosis of a tuberculous hip was really a diagnosis of inflammation of the joint, the tuberculous nature being a matter of assumption, to which little weight was added by opsonic estimation. He had seen many cases regarded as tuberculous and answering the tests which were not really due to tubercle. He thought that many so-called tuberculous joints which got well were instances of infection of the joints by another organism, and not by the tubercle bacillus. His experience with tuberculin agreed with that of the previous speakers, but he had seen cases which did not improve in the ordinary way suddenly begin to get well when put upon tuberculin. He suggested that some of the successes following tuberculin treatment were due not to it but to some unknown factor not yet understood.

Mr. J. P. LOCKHART MUMMERY advocated and practised conservative treatment, merely opening abscesses through a small incision, removing caseous material, and immediately suturing the wound. In septic infection, after scraping the sinuses, plugging them with gauze soaked in 5 per cent. formalin often gave good results.

SECTION OF BALNEOLOGY AND CLIMATOLOGY.

Treatment of Gastro-hepatic Dyspepsia at Vichy, Carlsbad, and Cheltenham.

A MEETING of this section was held on Dec. 13th, 1911, Mr. G. H. THOMPSON, the President, being in the chair.

Dr. GUSTAVE MONOD (Vichy), in a paper entitled "The Treatment of Gastro-hepatic Dyspepsia at Vichy, Carlsbad, and Cheltenham," briefly sketched and contrasted hydrological treatment as carried out at Vichy, Carlsbad, and Cheltenham, and pointed out that cases of gastro-hepatic dyspepsia might be treated with equal success at each of these health resorts. He particularly emphasised the fact that chemical analysis of the waters did not explain their therapeutic effect, and further, that waters of widely different chemical composition produced the same clinical results. He affirmed that the clinical standard was the only reliable one and should form the basis of all hydrological treatment. He had been particularly impressed with the therapeutic resources of Cheltenham, and gave it as his opinion that the waters of this spa, if they were hot, would unite the merits of Vichy with those of Carlsbad a combination which would confer world-wide renown on a British health resort. He deplored the meagre quality of the literature on Cheltenham from a clinical point of view, and maintained that, unless well-defined clinical indications were furnished, continental physicians would not feel encouraged to send their patients to an English spa.

Dr. C. W. BUCKLEY emphasised the value of comparative studies of spas such as Dr. Monod had laid before them. He deplored the fact that Cheltenham did not make more use of its waters, which possessed unique qualities. He briefly discussed the origin of the under-current douche as used at Vichy, and said that while Plombières claimed its invention it probably originated independently at many different spas.

Dr. S. P. SUNDERLAND also discussed the paper, and Dr. MONOD replied.

DEVON AND EXETER MEDICO-CHIRURGICAL SOCIETY.

Diagnosis and Treatment of Carcinoma of the Rectum.

A MEETING of this society was held at the Royal Devon and Exeter Hospital on Dec. 9th, 1911, Mr. J. M. ACKLAND, the President, being in the chair.

Mr. H. J. WARING (responding to a request from the President and Council of the society) gave a lecture on the Diagnosis and Treatment of Carcinoma of the Rectum. He began by briefly referring to the anatomy of the pelvis, laying special stress on the distribution of the lymphatic and vascular systems and the peritoneal attachments. He pointed out that next to the stomach the rectum was the most often invaded portion of the alimentary tract. He considered that errors in diagnosis were as a rule made rather through incompleteness in examination technique than through ignorance. For this reason he advocated a routine method of examination on the following lines where rectal disease was suspected: 1. Inquiry into the history of the case, and if possible the inspection of a bowel evacuation without aid of aperient or enema. 2. Local examination, preceded by aperient or enema. This local examination should include: A. Inspection of anal ring. B. Digital examination, in: (*a*) left lateral position; (*b*) genu-pectoral position; (*c*) sitting position (here growths become sometimes accessible where otherwise no abnormality could be detected in the bowel); (*d*) bimanual, either with or without the aid of an anæsthetic (in the case of the female the combined vaginal and rectal examination was extremely valuable); and (*e*) instrumental by the proctoscope (two forms of which were shown to the meeting). Mr. Waring lamented the fact that patients were treated for coexistent piles or by dilatation with bougie for stricture when an examination conducted on the above lines would in many cases have revealed disease at a moment when the question of operation for its complete removal could be hopefully laid before the patient. He also counselled the advisability of removing at the time of examination a small portion of growth in doubtful cases. In the case of disease at some distance from the examining finger the growth could be conveniently removed through the proctoscope by specially constructed forceps. The portion so taken away might show the presence of squamous-celled carcinoma when removed from the lower two inches of the bowel; columnar-celled carcinoma, (adeno-carcinoma, scirrhus carcinoma, or colloid carcinoma); or sarcoma, extremely rare and only noted once in his personal experience, the patient being a boy. Secondary growths might be found in: (*a*) the inguinal glands (growths in the neighbourhood of the anal margin frequently spread to these glands); (*b*) sacral; (*c*) lateral pelvic; (*d*) lumbar; and (*e*) supraclavicular (invasion of these glands occurred in advanced cases and indicated disease in the upper bowel and extension *viâ* the thoracic duct; operation here was, of course, entirely negatived). The liver and lung were the organs most frequently the seat of secondary visceral growths. Mr. Waring next dwelt on the points making for or against the advisability of an operation, attaching special importance to the locality of the growth and its exact relation to surrounding structures, such as the bladder, vesiculæ seminales, prostate, or in the female the uterus and vagina. Where invasion of the bladder was suspected, examination with the cystoscope in the male, or the speculum in the female, should always be undertaken before operation was decided upon. If then it was seen that the growth had extended to or through the vesical wall the patient would be saved from a fruitless operation. In the absence of visceral secondary growths lymphatic dissemination was not necessarily a bar to operation. As regards the general condition of the patient the state of the renal functions should be carefully ascertained. Obese patients, and more especially obese male subjects, were the least suitable for the abdomino-perineal operation. Turning to the varieties of operation, there were five classical methods:—1. Perineal (Cripps). Suitable only for growths within reach of the finger. 2. The posterior, or Kraske's, operation with division of the sacrum. The originator did not now recommend it owing to the unsatisfactory position of the resulting anus and the high mortality. 3. The vaginal method. Here disease might sometimes be eradicated by an incision carried through the posterior vaginal wall, and in some cases (one of which was cited by Mr. Waring) excellent results had been obtained, both as to function and freedom from recurrence. 4. The abdominal method which aimed at removal of the diseased portion of bowel and end-to-end anastomosis. A splint could be conveniently employed by means of a rubber tube with one extremity protruding at the anal margin. 5. The abdomino-perineal method. In describing this procedure Mr. Waring strongly cautioned against attempting this operation when obstruction was present, and he advised in such circumstances that an inguinal colostomy should be performed at least two weeks prior to the actual excision

of the diseased bowel. The permanence of the colostomy opening would then, of course, depend on the length of bowel excised and the feasibility of bringing it down. He showed from his own experience that sufficient length could generally be obtained by digital separation of the peritoneum laterally, and in one case he had partially freed the splenic flexure. When excision was undertaken and it was possible to unite the bowel to the anal margin he strongly advised that this should be done. The lumen should be either closed by stitches for a couple of days or a rubber tube sewn in so as to minimise contamination of the wound. From his own personal experience Mr. Waring could speak hopefully of the operation as regarded both functional results and freedom from recurrence, and at the close of his lecture he showed two specimens of excised bowel with extensive growth successfully removed, one of which related to a patient operated upon some five years ago who remained free from recurrence and in the enjoyment of good health.

A vote of thanks, proposed by Mr. A. C. ROPER and seconded by Dr. P. M. DEAS, was unanimously accorded to Mr. Waring. In the evening the society entertained Mr. Waring at its annual dinner, Dr. WILLIAM GORDON being in the chair.

EDINBURGH OBSTETRICAL SOCIETY.

Abdominal Operations for Cancer of the Cervix and Corpus Uteri.

A MEETING of this society was held on Dec. 13th last, Dr. J. HAIG FERGUSON, the President, being in the chair.

Dr. F. J. MCCANN, of London, gave a lantern demonstration with explanation of the technique of the more extensive Abdominal Operations for Cancer of the Cervix and Corpus Uteri. The preliminary operation is performed in a different room, with different instruments and gloves, and is carried out just before the abdominal one. At the first operation the necrosed part of the cervix is scraped and cauterised with the iron cautery. The vagina is swabbed with a 5 per cent. solution of silver nitrate, the excess dried out, and a large piece of iodoform gauze is packed into the vagina and so arranged as to admit of easy removal. The patient is then wheeled into another room and placed in the Trendelenburg position. Dr. McCann described in detail the abdominal operation by which the uterus, appendages, and parametrium are removed, the cancer being enclosed in a bag of vagina. Cystitis after operation is prevented by emptying the bladder by catheter every four hours from the first day onwards, so that the urine is not allowed to accumulate in the bladder, and on each occasion it is completely emptied. A certain amount of vesical paresis is present in every case owing to the extensive separation of the bladder. Dr. McCann had in 41 cases of cervix carcinoma a mortality of 2, though in 1 case he was not responsible for the after-treatment, and in 24 cases of cancer of the body of the uterus he had 1 death.

Dr. A. H. F. BARBOUR was very much interested in Dr. McCann's paper and more particularly in his good results. The importance of tying the ovarian arteries was obvious. He was surprised to see the frequency of cancer of the body of the uterus in comparison with cancer of the cervix in Dr. McCann's series of cases.

Dr. N. T. BREWIS said that Dr. McCann's description of the operation was the clearest he had heard or read. The operation was commonly called Wertheim's, but he should not get the credit of it because the only part he was entitled to was the use of vaginal clamps; many others had worked at it before Wertheim. Until quite recently he (Dr. Brewis) had considered that the vaginal operation gave as good results as the abdominal: at any rate he felt that if the disease was not confined to the uterus there was no good doing any other operation. Now, however, he was a convert to the abdominal operation, which gave the possibility of determining whether the case was operable or not. He agreed with Dr. McCann that cancer of the body was almost as common as cancer of the cervix and almost as virulently malignant.

Professor J. A. C. KYNOCH (Dundee) mentioned that from observation at his visits to German clinics they got the cases in a much earlier stage than surgeons did in this country. His own experience of vaginal hysterectomy was very discouraging. The protection of the abdominal wound was of great importance in order to prevent infection.

Dr. W. FORDYCE said that his results had been somewhat disappointing with Wertheim's operation. As regards separation of the bladder, he considered if there was any risk of tearing into the bladder because of infiltration, then the operation had better not be continued, because there was probably infection.

Mr. E. W. SCOTT CARMICHAEL considered the abdominal operation the only operation which could be entertained on scientific and pathological grounds for the radical cure of cancer, and he never intended in the future to do a vaginal hysterectomy for an operable case of cervical cancer. Wertheim in his recently published results had in 500 cases a mortality of 15 per cent., while Dr. McCann in 41 cases had 2 per cent. These latter good results were due to the excellent technique of Dr. McCann. He was convinced that in pelvic operations it was necessary to do an anatomical dissection as far as possible. Ligaturing in a mass was objectionable.

The PRESIDENT said Dr. McCann had shown that the mortality of abdominal hysterectomy for cancer could be brought down practically to that of vaginal hysterectomy. It was absolutely impossible to remove all the glands from the pelvis and abdomen. It was known that in only one-third of the cases of cancer of the cervix were the glands post mortem found to be involved at all, and these were chiefly in advanced inoperable cases. In his experience, recurrence took place not so much in the glands as in the scar. The great advantage of the abdominal operation was that one could isolate the infective mass and prevent recurrence; the main point was to remove the parametrium.

Dr. MCCANN, in reply, said that the clamp used by Wertheim was not his own, and the idea of closing the bag of the vagina was done long before his time; but Wertheim had definitely and consistently followed this operation for many years and had placed on record the largest number of tabulated cases. Entire removal of glands was not possible, but as thorough a removal as possible greatly improved the after-results. An interesting point was that in the abdominal operation the recurrence was in the glands, whereas in the vaginal operation it was in the scar. The complete separation of the bladder should not be done until after the ureters had been separated. His objection to previous curetting some days before was that it was apt to be followed by sepsis and inflammation of the bladder, owing to the packing becoming infected. The selection of cases was very important, lest the operation should be brought into discredit. His object had been mainly to show the results obtainable by attention to technique and especially to hæmostasis.

ROYAL ACADEMY OF MEDICINE IN IRELAND.

SECTION OF SURGERY.

Veno-venostomy in Ascites.—Volvulus of the Spermatic Cord.—Treatment of Surgical Tuberculosis by "Dioradin."

A MEETING of this section was held on Dec. 8th, Mr. W. I. DE C. WHEELER being in the chair.

Sir CHARLES BALL read notes of a case of Ascites in an alcoholic woman. On Nov. 30th, 1910, she was treated by lymphangioplasty, but this operation was unsuccessful in preventing the accumulation of ascitic fluid. On Dec. 21st an incision was made on the left saphenic opening down the thigh over the course of the vein for about 10 inches. The vessel was ligatured and cut across below and dissected out up to the point at which it went in deeply to join the femoral vein. The abdomen was opened by an oblique incision over Poupart's ligament, and the lower edge of the peritoneal incision was separated from the pelvis until the femoral ring was exposed. The cut end of the saphena vein was brought through the canal into the subperitoneal tissue. An incision was made through the outer layer of peritoneum of the meso-colon, and a large sigmoid vein was found. By separating the peritoneum from the incision in the meso-colon the primary wound in the abdominal wall was easily reached, so that the saphena vein could be brought up into the meso-colon extraperitoneally. The intestinal vein was anastomosed into the saphena vein, and on removing the clamps blood was seen flowing into the saphena vein without leakage at the line of

union. Before closing the abdomen the side of the silk drains on the opposite side were felt, and it was found they had been smoothly covered by lymph and were useless. Recovery was rapid, but fluid re-forming moderately she was tapped again on Jan. 18th. She remained well until two months ago, when she began to drink heavily, and the fluid re-formed. Had she given herself fair-play she probably would have remained longer well.—Mr. WHEELER said that what Talma and Morison had attempted had been successfully accomplished by Sir Charles Ball. He had found the Talma operation to work well in a case of ascites, but no patient suffering from jaundice, cirrhosis of the kidney, or heart affection could be considered suitable for such an operation. Patients suffering from atrophic ascites were the most favourable cases.—Mr. K. E. L. G. GUNN said he had once attempted to anastomose the ovarian and portal veins, but failed. In these Morison cases the patient either improved immediately or there was no improvement at all. If the improvement was due to the anastomosis being satisfactory, one would expect it to be of a gradual nature. He would prefer to try the operation suggested by Sir Charles Ball.—Mr. R. A. STONEY said that although he considered the operation of Sir Charles Ball an excellent one, lymphangioplasty could not be dismissed as an absolute failure. In a case of polyserositis he had found it most satisfactory.—Sir CHARLES BALL, replying, said his results with lymphangioplasty had been most disappointing.

Mr. A. A. MCCONNELL read notes of a case of Volvulus of the Spermatic Cord in a boy of 15, who was suddenly seized with severe pain in the right groin when he was sitting on his right foot with that leg crossed tailor-fashion beneath him. He had several attacks of vomiting. Strangulation of an incomplete inguinal hernia was diagnosed, and the case was operated on. The external oblique aponeurosis having been defined, what appeared to be the fundus of a hernial sac presented between the pillars of the ring. On opening the sac what appeared to be a coil of intestine was seen, covered by peritoneum and intensely congested. The sac came to an end at the internal ring, and the coil of supposed gut did not pass to the region of the ring. The finger could be passed freely downwards into the tunica vaginalis. The testicle was pulled up, and the supposed coil of intestine was found to be formed by a loop of the spermatic cord twisted on itself for two turns. All the constituents of the cord, including the vas, were included in this twisting of the loop. As the condition of the vessels would be incompatible with the maintenance of the blood-supply of the testis, and as necrosis of the latter often ensued after untwisting the cord in cases of torsion, the testicle was removed. The testis was apparently normal and could be palpated without pain or tenderness. The only explanation for the absence of testicular swelling was that probably the arteries and veins had been occluded simultaneously, so that marked venous congestion could not take place.—Mr. WHEELER and Sir CHARLES BALL found it difficult to understand how an ordinary torsion of the cord could occur.—Mr. STOKES spoke of his experience of two cases of this kind. In neither was there any trace of atrophy in the testicle after the torsion had been reduced.—Mr. STEVENSON asked if it was found easy to untwist the cord.—Mr. MCCONNELL, in reply, had no theory to advance as to the causation of the condition. He did not think, seeing the way the cord was involved, that the blood-supply of the testis could have been carried on by that of the tunica. It was fairly easy to untwist the cord, but that did not satisfy him as to its safety. In another such case he would be inclined to leave the testis.

Mr. STONEY, in a paper on the Treatment of Surgical Tuberculosis by "Dioradin," stated that Dr. Bernheim visited the Royal City of Dublin Hospital last August and having examined several cases of various forms of surgical tuberculosis gave each patient an injection of "dioradin," leaving a supply to continue treatment. Fifteen cases had received one course of injections. Each course consisted of 40 injections of 1 c.c. or less (according to age) of "dioradin" into the gluteal muscles, the first 30 on consecutive days and the last 10 on alternate days. Dr. Bernheim advised at least two courses of injections given with a fortnight's interval. The results might be summarised as follows. In five cases without secondary infection there was one apparent cure (Case 1, Pott's caries), and the other four cases all greatly improved, and would probably result in cure after further treatment (Case 4, tubercular knee, Case 6, tubercular tarsus, Case 9, advanced tubercular hip, and Case 10, early tubercular hip). In ten cases with secondary infection there was one apparent cure (Case 5, with multiple tubercular foci); two cases were greatly improved and appeared likely to result in cure after a further course of injections (Case 3 and Case 11, both advanced tubercular hips); four cases showed some improvement (Case 2, tubercular cystitis, Case 13, tubercular peritonitis and fibroid phthisis, Case 14, lupus, and Case 15, phthisis and enlarged cervical glands). And finally three cases showed no improvement (Case 7, multiple tubercular foci, Case 8, hip disease, and Case 12, tubercular cystitis). Of these three, the case of cystitis was distinctly worse, but there was no reason to suggest that the treatment was to blame for this; he was admitted to hospital only to try to get him sufficiently improved to allow him to go back to the country to die. The disease had lasted several years, and his kidneys were almost certainly affected also. The case of the hip was never proved to be tubercular; and in any case the septic element present always appeared the more important. The case of multiple tubercular foci, after improving, developed whooping-cough and relapsed; however, a few days ago he was reported almost perfectly well, only one very small sinus still remaining with a very slight daily discharge. Many of these cases had already been in hospital under various forms of treatment without improvement for many months before the injections of "dioradin" were started.—Mr. WHEELER said it was hard to see how intramuscular use of radium could do good. He attributed the improvement as much to extra attention given to them as the "dioradin."—Dr. W. M. CROFTON referred to the treatment of phthisical cases with iodoform given intravenously or intramuscularly. Combined with tuberculin this treatment had the effect of bringing down the temperature, reducing the sputum in advanced cases. Iodoform obviated the reaction after tuberculin. He had seen "dioradin" fail in three advanced cases of pulmonary tuberculosis.—Mr. STEVENSON said it was of interest that those cases in which there was no secondary infection gave the best results. He suggested combining "dioradin" treatment with a vaccine for the secondary infection. The great objection to the use of the drug was the uncertainty as to its exact composition.—Dr. T. P. C. KIRKPATRICK was not favourably impressed by it so far. He had not yet seen any case which could be called a "cure."—Mr. STONEY, replying, said that most of his patients had been under treatment for a considerable time without improvement, but that as soon as "dioradin" was injected it did them some good. It had been definitely demonstrated by test-tube experiments that the combining of radium chloride with menthol and iodine increased its power of destruction of the tubercle bacillus. Some cases of secondary infection thus treated by him had improved considerably.

UNITED SERVICES MEDICAL SOCIETY.—A meeting of this society was held on Dec. 13th, 1911, at the Royal Army Medical College, Major E. B. Waggett, R.A.M.C. (T.), being in the chair.—Fleet Surgeon D. J. P. McNabb, R.N., read a paper on the Functions of Hospital Ships in Peace and War. The lecturer, who has had medical charge of the Royal Navy hospital ship *Maine*, spoke of the services rendered in peace by a hospital ship constantly ready to receive the more serious cases of illness and accident from the fighting ships of the fleet at sea or in places with no suitable accommodation on shore, thus relieving the strain on the sick berth accommodation of the fleet and providing the sick with air-space, nursing, quiet, and general comfort unattainable in a man-of-war. In war time the duties of hospital ships were more exacting and important. It was necessary to clear fighting ships of their wounded as soon as possible after action, both for the welfare of the injured and because a ship encumbered with wounded would be much hampered should it be necessary to renew the action. Many interesting details were given as to the best methods of transport of wounded from the fighting ships to the hospital ships, and the lecture was illustrated by models of appliances for conveying injured men. The best position to be taken up by the warship and hospital ship during the transference, using the larger vessel as a breakwater, so that the boats might have as smooth water as

possible, was dwelt on. When fighting was taking place on land, but in the vicinity of the sea, in many places (such as the West Coast of Africa) the hospital ship was an invaluable accessory, providing the sick and wounded with an accommodation, attention, and comfort otherwise impossible. Another function of hospital ships in peace and war was the transport of large numbers of sick either from the seat of war home or from a foreign hospital to a home one; the Royal Naval hospital ship *Maine* had been largely used for this purpose when not in attendance on a fleet and by so doing had greatly relieved the congestion of foreign hospitals and brought the sick to a climate where their prospects of speedy recovery were considerably enhanced. The lecturer stated that in his opinion the ideal hospital ship was one of from three to four thousand tons, with a speed of about twelve knots, and with accommodation for about 240 sick in peace time, which accommodation could be increased in war time by about 100. Fleet-Surgeon McNabb also considered it desirable that each hospital ship should have four wards on the boat deck for cases of infectious disease.—Deputy-Surgeon-General J. J. Dennis, R.N., Major W. S. Harrison, R.A.M.C., Major Waggett, and Inspector-General R. Bentham, R.N. (retired), took part in the discussion.

LEEDS AND WEST RIDING MEDICO-CHIRURGICAL SOCIETY.—The first clinical meeting of this society was held on Dec. 15th, 1911, Mr. H. Littlewood, the President, being in the chair.—The President showed eight cases of Gastric Ulcer successfully treated by excision of the ulcer. In each case a cure had resulted.—Dr. H. H. Greenwood showed a case of Melanotic Sarcoma of the Neck in a man aged 67, treated periodically for eight months with Coley's fluid, with apparent recovery.—Dr. A. G. Barrs showed a man, aged 36, who exhibited all the classical signs and symptoms of Locomotor Ataxia, which began after a very severe shock. There was no history or sign of syphilis.—Mr. W. Thompson showed a case of Gastro-enterostomy, with Recurrent Symptoms, in a man aged 29; also a case of Xerostomia in a female aged 23, associated with recurrent swelling in the parotid gland.—Dr. W. H. Maxwell Telling showed a case of Unilateral Facial Sweating of 12 years' duration in a male aged 60. Also a case of "Aleukæmic" Leukæmia with a massive Spleen in a man aged 52. The appearance was one of chronic cyanosis rather than of anæmia. The blood showed a high red-cell count and a comparatively low white-cell count; the diagnosis of myelogenous leukæmia was based on the differential white-cell count. The condition was largely stationary, though there had been some general improvement under arsenic.—Mr. H. Collinson showed: 1. A man, aged 41, in whom Symptoms of Musculo-spiral Paralysis followed immediately after fracture of the humerus in March last. At the operation the musculo-spiral nerve was found contused between the fragments. The fracture was fixed with a Lane's plate, and the nerve was protected by muscular tissue. Restoration of function in the extensor muscles commenced after five months, and was already nearly complete. 2. A boy, aged 15, with a similar condition.—Dr. T. Wardrop Griffith showed a case of Lead Encephalopathy with marked Ataxia in a woman of 34. Symptoms of lead poisoning began after taking certain pills.—Mr. J. F. Dobson showed a man, aged 35, who fractured the lumbar spine in July last. On Sept. 1st laminectomy was performed (first, second, and third lumbar vertebræ), and the cauda equina was found compressed and the dura mater torn. The patient was now commencing to walk with the aid of a walking chair.—Dr. Alexander Sharp showed a case of Hyperplasia in a female aged 21, involving the lingual tonsil, epiglottis, aryepiglottic folds, and the arytenoids, and unaffected by any form of treatment.—Mr. R. Lawford Knaggs showed a woman, aged 26, admitted in December, 1908, for a Pistol Wound of the Brain, upon whom trephining was performed. The skiagrams showed the bullet in the right occipital lobe, some distance above the tentorium.—Cases were also shown by Dr. T. Churton, Mr. J. A. Coupland, Mr. A. L. Whitehead, and Mr. G. Constable Hayes.

NORTHUMBERLAND AND DURHAM MEDICAL SOCIETY.—A meeting of this society was held in the Royal Victoria Infirmary, Newcastle-on-Tyne, on Dec. 14th, 1911.—After a demonstration of the Use of the Œsophagoscope under local anæsthesia on a series of patients suffering from carcinoma, stricture following nitric acid burns, doubtful stricture—i.e., a female patient who had had attacks of obstruction intermittently for years, Mr. C. W. M. Hope delivered an address on Carcinoma of the Œsophagus. He referred to the unsatisfactory means hitherto used in the diagnosis and treatment of the condition, and considered its symptomatology and pathology. Under "examination of the patient" he included in the following order: (1) external glandular enlargement, &c.; (2) mouth, pharynx and larynx, by laryngoscopic mirror; (3) chest, for evidence of aneurysm or pressure of growth; (4) X rays, with the aid of bismuth cachets, meals, &c.; and (5) endoscopic examination, either by local or general anæsthesia. This last was described at length. He classified the treatment under the following headings: (1) dilatation; (2) dilatation with intubation; (3) gastrostomy; and (4) radium, following a dilatation. Dilatation with intubation he considered the most advisable method of treatment, and advocated it strongly. He described a modification of Symonds's tube, a silver flexible stilette being passed through the lumen and a vulcanite front being fixed to it. He referred to several cases in which temporary improvement had resulted from radium, mentioning in particular one case of septic fungating carcinomatous stricture. After 21 months some stricture was still present, but ulceration had gone, and the œsophagus was lined throughout with apparently normal mucous membrane. The patient had gained about a stone and could swallow solid food well. He emphasised the necessity for caution in diagnosing spasm of the œsophagus in middle-aged patients, and quoted such a case with an extensive post-cricoidal carcinoma.—A lantern demonstration illustrating the points brought out followed the address. There was a short discussion.

NEW LONDON DERMATOLOGICAL SOCIETY.—At a meeting held on Dec. 14th, 1911, Dr. P. S. Abraham, the President, being in the chair, Dr. W. Knowsley Sibley showed: (1) A young woman with Bazin's Disease and Scrofulodermia (shown at a previous meeting) to illustrate the beneficial effect of radiant heat treatment, several of the granulomatous areas having become completely absorbed; (2) a young woman, aged 35, with an acute outbreak of Lichen Planus, associated with a chronic seborrhœic condition of the scalp and body; (3) a child of 14 months with Bullous Impetigo affecting the Buttocks; and (4) a boy, aged 15, with Atypical Molluscum Contagiosum upon the Back. The lesions, three in number, were of the size of a small nut and were semi-pedunculated, but the contents of one of them after incision revealed the presence of the characteristic molluscum bodies.—Dr. G. Norman Meachen showed: 1. A man, aged 25, with Lichen Planus, in which the formation of small bullæ had occurred, chiefly upon the legs. The rarity of this complication and its relation to the administration of arsenic were commented upon. 2. A man with a Rodent Ulcer upon the Side of the Nose, following a scratch inflicted 12 years ago. 3. A case of Pruritus and Pigmentation of the Skin in a man, aged 56, who had been informed 10 years ago by a well-known authority that he was suffering from Addison's disease. At the time of the meeting he was a well-nourished man, and he presented a faint macular and scaly eruption suggestive of a pityriasis rosea.

ROYAL SANITARY INSTITUTE.—The next Congress of the Royal Sanitary Institute will be held at York from July 29th to August 3rd, 1912, under the presidency of the Archbishop of York. Sir Shirley Murphy will preside over the Section of Sanitary Science and Preventive Medicine, Sir Thomas Oliver over the Section of Industrial Hygiene, and Dr. Mary Scharlieb over the Section of Hygiene of Infancy and Childhood, while the President of the Conference of Medical Officers of Health will be Professor A. Bostock Hill.

MEDICAL MAGISTRATES.—Mr. John Cosmo Stuart Rashleigh, M.D., B.C. Cantab., L.S.A., has been placed on the commission of the peace for the county of Devon; Mr. Walter Henry Fox, L.D.S. Eng., dental surgeon to the Gloucester Children's Hospital, has been placed on the commission of the peace for the county of Gloucester; and Mr. Matthew Elder, M.B., C.M. Edin., and Mr. William Charles Devereux, M.B., B.C. Cantab., have been appointed magistrates for the Tewkesbury (Gloucestershire) borough bench.

Reviews and Notices of Books.

Sir John Burdon Sanderson: A Memoir. By the late Lady BURDON SANDERSON. Completed and edited by his Nephew and Niece. With a Selection from his Papers and Addresses. With photogravure frontispiece and three portraits. Oxford: The Clarendon Press; London: Henry Frowde. 1911. Pp. 315. Price 10*s.* 6*d.* net.

THIS memorial volume is divided into two parts, about one-half being devoted to the memoir itself and the remainder to reprints of Sir John Burdon Sanderson's papers and addresses. The memoir consists of nine chapters, of which the first four deal with his parentage and boyhood, youth and education. They were written by the late Lady Burdon Sanderson, while for the remaining chapters, dealing with his earlier and later scientific work, his removal to and life at Oxford, and his personal characteristics and opinions, his nephew and niece, J. S. Haldane and E. S. Haldane, are responsible. Much of the biographical detail here dealt with was included in our obituary of this distinguished man, published in THE LANCET of Dec. 2nd, 1905, but it may not be amiss here to cull a few points and considerations not there recorded. He was intended, we are told, for the profession of the law, but as a lad his inclinations turned towards natural science, and his early relationship with Dr. Mortimer Glover led him to the choice of the profession of medicine. He matriculated at the University of Edinburgh on Nov. 2nd, 1847, in the name of John Scott Sanderson. It was not until a few years later that he habitually adopted his father's ancestral name of Burdon. The professors that most influenced him in his early professional career were Balfour (botany), Goodsir (anatomy), and Hughes Bennett (institutes of medicine). It is stated that in 1841 the microscope, now so familiar to every student, had not found its way into either the ward or the physician's consulting room. He duly became, like so many prominent Scottish physicians and surgeons, president of the Royal Medical Society, and interesting extracts are given from the address he delivered before that society.

In Paris he studied organic chemistry under Wurtz, and followed the lectures of Coste on embryology and those of Bernard on physiology. There can be little doubt that to the influence of Bernard is largely due the benefit which Sanderson derived from his residence in Paris during 1851–2. In 1853 he married Ghetal, elder daughter of the Rev. Ridley H. Herschell, and "the happy life in common which then began continued for 52 years." After ten years' service as medical officer of health of Paddington the reason of his retirement in 1865 was the antagonism induced in some of the vestrymen on account of his proceeding to Germany at the request of the Government to investigate the epidemic of cerebro-spinal meningitis then raging in and around Dantzig. His valuable investigations on diphtheria, into the practice of vaccination, and on cattle plague are well known, and have already been recorded in these columns. His later career is followed in detail, including his work at the Middlesex and Brompton Hospitals, the Brown Institute, and University College, London. With the publication in 1873 of the "Handbook for the Physiological Laboratory," by Klein, Burdon Sanderson, Foster, and Lauder Brunton, the crusade against experimental physiology, known as the anti-vivisection movement, came into notice. The foundation of the Physiological Society was one outcome of this movement. Those who are interested in the early history of this still clamant question will find full details in Chapter VI. of the memoir, which deals with Sanderson's later work in London. The story of the storm that broke out at Oxford in reference to the expenditure of £10,000 to equip a laboratory for Sanderson, on his appointment as Waynflete Professor of Physiology, is well told. When the decree was submitted to Convocation on June 5th, 1882, it met with such strenuous opposition on scientific, financial, and humanitarian grounds that it was carried by a majority of only three in a house of 173. The assistance given by Sir Henry Acland was most valuable. Equally vividly the story is recounted of his varied work, success, and stimulating activity during the 23 years (1882–1905) spent at Oxford. Sanderson held that all the processes which a physiologist can investigate are in ultimate analysis physical and chemical in nature, and he saw clearly the importance of intracellular ferments for the solution of difficulties in the physico-chemical interpretation of cell activity. The elaborate paper on Vegetable Reproduction which in 1854 he prepared for Todd's Cyclopædia of Anatomy and Physiology shows the unity of his aims through his long career as a biologist.

No memoir of Burdon Sanderson would be complete without mention of the wife to whom he owed so much. "A more devoted or helpful wife she could hardly have been, and in addition to that devotion she encouraged her husband in his work in every way in her power." Thus the authors, and all who had the inestimable privilege of knowing Lady Sanderson, will agree with this estimate of her. We can well understand that Sanderson never seemed happy when she was not near, and that in his later days this became increasingly evident. Her greatest work was the love and support which she gave so fully and ungrudgingly to her distinguished husband.

We feel sure that many readers will be glad to possess in a collected form the papers and addresses that make up the second part of this volume. They are: On the Excitability of Plants (1884), On the Study of Physiology (1883), Address delivered to the British Association (1889), Presidential Address to the British Association (1893), Ludwig and Modern Physiology (1896), Cellular Pathology (1900), and Our Duty to the Consumptive Bread-earner (1901).

Altogether this is a delightful memoir of a charming, lovable, and striking personality, of a man whose life was devoted unselfishly to the successful pursuit of truth, and who has left the impress of his labours on the progress of that science to which he devoted his life.

A Handbook of Practical Treatment. By Many Writers. Edited by JOHN H. MUSSER, M.D., LL.D., Professor of Clinical Medicine in the University of Pennsylvania; and A. O. J. KELLY, A.M., M.D., Assistant Professor of Medicine in the University of Pennsylvania. Vol. II. London and Philadelphia: W. B. Saunders Company. 1911. Pp. 865. Price £3 15*s.* net the set (three volumes).

THE second volume of this notable work upon treatment fully bears out the promise of the first, which we reviewed in THE LANCET of Oct. 21st, 1911. The subjects included in this volume are diseases of the cardio-vascular system, the infectious and animal parasites. Each article is a carefully written presentation of the treatment of the condition with which it deals and the principles upon which the treatment is based, while the explanation of its effects is given where this is practicable.

The first article is contributed by Sir T. Clifford Allbutt and is devoted to the treatment of diseases of the cardio-vascular system. It extends to 150 pages and affords an interesting and critical account of the treatment of the individual diseases and disorders of the heart and blood-vessels. The arrangement of the subject-matter is good and is convenient for reference, while the literary style in which it is expressed is the dignified but happy one we are accustomed to expect from this distinguished and cultured writer. Sir Clifford Allbutt, while giving his own personal experience of

various treatments, is careful to state the views of other authorities, usually with references. Mr. Clinton T. Dent, in a short article on the surgery of the heart, describes paracentesis of the pericardium, cardiolysis for pericardial adhesions, and the surgical treatment of thoracic aneurysm. In regard to the removal of the fluid of non-purulent effusions into the pericardium, Mr. Dent thinks that incision, with subsequent dissection down to the pericardial sac, ought to be more frequently employed, since he regards it as safer and more likely to succeed than puncture.

The treatment of typhoid fever is discussed in an interesting and exhaustive manner by Dr. Rufus I. Cole. Considerations of prophylaxis and disinfection are first reviewed, and then the subject of prophylactic vaccination is critically examined. The attempts at specific treatment by antitoxins and serums are referred to, and then the general management and nursing of patients suffering from this disease are described. The subject of diet is dealt with at some length, and the various views at present current in regard to the feeding of these cases are subjected to careful criticism. The uses of antipyretic drugs and measures are described in full, and explicit directions in regard to the bathing of these cases are given, together with numerous illustrations in the form of reproductions of photographs. The treatment of symptoms and complications is also fully considered. Dr. John M. T. Finney describes the treatment of the surgical complications of typhoid fever in a short but practical article. The treatment of pneumonia is examined by Dr. Hobart Amory Hare in a well-written and thoughtful contribution. Diphtheria is dealt with in two separate sections: the first by Dr. George H. Weaver, on the specific and general treatment; the second by Dr. John H. Jopson, on intubation and tracheotomy, which are carefully described. The directions given in regard to the administration of antitoxin are explicit, and brief reference is made to the "serum reaction" as a manifestation of hypersusceptibility. Dr. Weaver also contributes the articles on scarlet fever, measles, and rötheln.

The treatment of tuberculosis as described by Dr. E. O. Otis extends to 120 pages with copious illustrations. The principles of sanatorium and home treatment, questions of diet, symptomatic and specific agents, are all discussed at length. Plans and illustrations of well-known sanatoriums are given, and numerous simple methods of carrying out open-air treatment at home are described and figured. Three methods of giving tuberculin are referred to—viz., the tolerance method, by giving small doses and gradually increasing them; the reaction method, giving such doses as will produce a mild reaction; and the opsonic index method of Wright. The first of these is the one recommended. The treatment of syphilis is fully and carefully considered by Dr. G. William White and Dr. Alfred C. Wood. The various methods of administering mercury are discussed, with their relative advantages and disadvantages. The use of "606" is briefly reviewed and a judicial attitude is advised in regard to this substance, and until its place in therapeutics is settled the writers of the article advise the practitioner to follow the older methods of treatment. A useful account of the various methods of treating infection by the gonococcus in its manifestations in both sexes is contributed by Dr. Edward Martin. The treatment of vaccinia, variola, and chicken-pox is described by Dr. Jay F. Schamberg, and that of cerebro-spinal fever, cholera asiatica, and plague by Dr. Llewellys F. Barker, while the subjects of yellow fever and dengue are dealt with by Dr. James Carroll. Dr. Alfred Stengel discusses the treatment of influenza and rheumatic fever in two practical and clearly expressed articles. Tetanus, rabies, anthrax, glanders, actinomycosis, Madura foot, and foot-and-mouth disease are briefly considered by Dr. Joseph C. Bloodgood and Dr. Alexius McGlannan, and pertussis, mumps, miliary fever, and glandular fever by Dr. Samuel McHamill. The treatment of dysentery is dealt with by Dr. Charles F. Martin, that of leprosy by Dr. Isadore Dyer, and that of typhus fever by Dr. John F. Anderson. In the last-mentioned article the importance of the body louse in spreading infection is emphasised, and a brief description is given of recent work upon the communicability of this disease.

The remainder of the book contains some special articles. The first of these is devoted to tropical diseases, which are admirably dealt with by Dr. M. J. Rosenau and Dr. J. F. Anderson. The second, by Dr. D. G. E. de Schweinitz, is devoted to the ocular complications of the infectious diseases, and gives a full and interesting account of the management of these serious and important conditions. A similar article on the aural complications of the infectious diseases is contributed by Dr. Charles W. Richardson, while the surgical treatment of the joint complications of the infectious diseases is discussed by Dr. Joel E. Goldthwait. The treatment of conditions due to animal parasites is considered at length by Dr. David Riesman. A full index is appended to this volume, rendering reference easy.

Delayed and Complicated Labour. By ROBERT JARDINE, M.D. Edin., M.R.C.S. Eng., F.R.F.P. & S. Glasg., F.R.S. Edin., Professor of Midwifery in St. Mungo's College, Glasgow; Obstetric Physician and Gynæcologist to the Glasgow Maternity and Women's Hospital. With 107 illustrations and 3 coloured plates. London: Henry Kimpton. Glasgow: Alexander Stenhouse. 1911. Pp. 351. Price 7*s.* 6*d.* net.

THE readers of Dr. Jardine's work entitled "Clinical Obstetrics" will welcome the appearance of this compact book. In it the author has refrained from publishing the details of illustrative cases, and has contented himself with giving the result of his experience. The work is therefore the outcome of the author's experience and not in any sense a compilation. The amount of material available in the Glasgow Maternity and Women's Hospital is so large that any book written by one of the physicians attached to this hospital must contain much of interest to obstetricians less fortunately placed. But little space, only so much as is necessary to render the part dealing with delayed or complicated labour quite clear to the reader, is devoted in this work to normal labour. On the majority of the problems of obstetrics Dr. Jardine holds clear and well-established views, and the student who consults this work may be sure that he will receive definite instructions as to what should be done in any complicated case of labour and how to set about it. In the treatment of fibroid tumours and ovarian tumours complicating pregnancy and labour the author is in agreement with the best teaching of the day, and deprecates all interference during pregnancy unless it is unmistakably indicated. As he points out, Cæsarean section with hysterectomy at full term is much better than hysterectomy during pregnancy, and in dealing with an ovarian tumour during labour the removal of the tumour and the subsequent delivery of the child through the natural passages is much better than the performance of Cæsarean section.

The cases cited of obstruction caused by the retraction ring or the ring of Bandl are of very great interest. Dr. Jardine accepts the view generally held that the ring of Bandl indicates the union between the upper and lower uterine segments, and that it does not coincide with the internal os, and he points out that cases occur in which the ring itself is the cause of the obstruction to delivery. This may be so either in cases of breech presentation with extended legs, or in normal presentation in which the ring forms in front of the presenting part and itself constitutes the obstruction. He refers to two cases, one under the care of Professor M. Cameron and one

under his own charge. The latter was a most interesting case "in which the membranes were intact and the cervix well dilated, but there was a well-defined ledge round about half of the canal in front of the head." The patient was put deeply under the influence of morphia, but as no relaxation occurred Cæsarean section was performed with a favourable result to both mother and child. Cases have been recorded of obstruction from the retraction ring, even with a normal pelvis. As the author points out, it may form in breech presentations with extended legs above the presenting breech but below the legs, and give rise to delay in the descent of the child. Dr. Jardine suggests that the causes of spasmodic contraction of the internal os may also be the cause of the formation of the retraction ring in these cases. In their treatment the injection of morphia is advised, and then manual dilatation of the ring under an anæsthetic. If this fails, then the performance of Cæsarean section if the child is alive, and even if the child is dead where it is likely that delivery by the natural passages may be dangerous.

Dr. Jardine has had considerable experience of cases of eclampsia, and the chapter devoted to this complication is a particularly good one. His treatment is characterised by a sound conservatism. He does not believe in the view that every case should be delivered as quickly as possible after the fits have commenced. We are glad to see that he lays stress in the preventive treatment on restraining the patient to bed and keeping her warm, a most important injunction. The curative treatment is carried out on the principle of getting the bowels, kidneys, and skin to act. Lately the author has been employing veratrone in doses of 1 c.c. by hypodermic injection, and finds that it has a marked effect in lowering the pulse-rate and tension, and in helping to check the fits. In decapitating, Dr. Jardine uses a modification of the blunt hook to which he has added a knife-edge, and maintains that this form is easier to apply than that of Ramsbotham, while for craniotomy he employs a modification of Auvard's cephalotribe, which seems to be a very efficient instrument.

We can cordially recommend this work as a well-written and trustworthy guide for student or practitioner.

An International System of Ophthalmic Practice. Edited by WALTER L. PYLE, A.M., M.D., Philadelphia. *Pathology and Bacteriology*, by E. TREACHER COLLINS, F.R.C.S. Eng., and M. STEPHEN MAYOU, F.R.C.S. Eng. London: Rebman Limited. 1911. Pp. 558. Price 21*s.* net.

THE need of a small text-book on the pathology of the eye has been long felt by teachers and students. The latter can scarcely be expected to buy an expensive four-volume treatise which has hitherto been the only monograph on the subject in the English language. It is unfortunate that in this case the publishers could not fix the price at a lower figure; none the less, the purchaser will find that he has obtained full value for his money.

The authors have been well advised to adopt a pathological, rather than an anatomical, classification of the disorders and diseases of the eye. Such a scheme places the subject more vividly before the reader and necessitates less repetition. It is the bolder line to adopt, and in many respects more difficult, but it is amply justified by results. The chapters are arranged as follows:—Aberration in development, neoplasms, derangements in the circulating fluids of the eye and of the vessels in which they are contained, injuries, inflammation, parasitic diseases affecting the eye, and degenerations. An appendix on practical methods gives a good *résumé* of the processes used for examining eyes microscopically, mounting macroscopic specimens, preparing vaccines, making Wassermann, agglutination, blood, and other tests.

In the chapter on development Mr. Treacher Collins has gathered together his many researches, amplifying and correlating them into a homogeneous and comprehensive survey. The subdivisions show the same logical sequence that characterises the work as a whole. Aberrations connected with the formation of the primary and secondary optic vesicles are first dealt with, introducing the reader to such anomalies as anophthalmia, cyclopia, coloboma of the retina and optic nerve, and so on. Aberrations connected with the invaginating surface epiblast deal with anomalies of the lens; aberrations connected with the invaginating mesoblast, with such conditions as persistence of the hyaloid artery, atypical development of the vitreous, congenital defects of the suspensory ligament (coloboma and ectopia lentis), and so on. Aberrations connected with the encircling mesoblast are held to account for congenital opacities of the cornea, congenital anterior staphyloma, buphthalmia, abnormalities of the iris and choroid, as well as albinism and melanosis affecting the eye. Lastly, aberrations connected with structures in the line of the orbito-nasal fissure and the formation of the eyelids include lacrymal abnormalities, meningo-encephalocele, cryptophthalmia, dermoids, and anomalies of the lids. The authors should note that *distichiasis* is the correct term, not "districhiasis"; the derivation of the word has nothing to do with that of trichiasis.

The second chapter, on neoplasms, is also excellent. Primary and metastatic new growths and cysts are adequately discussed, the only noteworthy omission being the extradural tumours of the optic nerve. Otherwise every growth of importance has been passed in review, some of the rarest manifestations being mentioned as exhibiting evidence of points important in the general pathology of the eye—e.g., melanotic carcinoma of the ciliary body. Derangements of the vascular systems of the eye include diseases of the vessel walls and their results, diseases due to changes in the blood, toxic amblyopias, and glaucoma. The anatomical part of the section on glaucoma is admirable, but we think that the description of the mechanism for the maintenance of the normal intra-ocular tension requires further elaboration. The authors draw a sharp distinction between "the lymph and the intra-ocular fluid." The latter is the fluid contained in the aqueous and vitreous chambers, and is a definite "secretion modified by the lining epithelium of the ciliary body." Most authors agree that it is lymph, even though it be modified in the manner suggested. The subject is of such surpassing importance in the pathology of glaucoma that it demands very precise and exhaustive treatment, even in a student's text-book. The pathology of increased intra-ocular tension is treated on the familiar lines of the theory almost universally accepted. A short section is devoted to the rationale of the treatment of primary glaucoma. Injuries and wounds of the eye are thoroughly discussed, their importance from the clinical, and especially the operative, point of view being particularly borne in mind.

The chapter on inflammation commences with a most useful review of the changes common to all inflammatory processes. There is a lucid account of the part played by the blood serum, and the many awe-inspiring terms adopted by modern pathologists are fully explained. The cytology of conjunctival inflammation incorporates Mr. Mayou's own work previously published as Hunterian Professor of the Royal College of Surgeons of England. The remainder of this chapter dealing with iridocyclitis, retinitis, and so on, is not quite up to the standard of the other chapters. The parasitic diseases of the eye, including bacteriology, are thoroughly well discussed, as are also the degenerations which affect the various structures.

It is gratifying to be able to give such unstinted praise to the scientific value of this work. The numerous mistakes of

grammar and punctuation, however, seriously detract from the ease and pleasure of reading it. We hope that this blemish will be removed in a future edition. The illustrations and printing are excellent.

Fortschritte der Naturwissenschaften Forschung. Herausgegeben von Professor Dr. E. ABDERHALDEN, Berlin. Dritter Band. Mit 153 text abbildungen. Wien: Urban and Schwarzenberg. 1911. Pp. 352. Price, paper, 16 marks; bound, 18 marks.

WHAT strikes one about this, the third, volume, describing the progress of recent investigations in natural science, edited by Professor Abderhalden, of Berlin, is that such a work would hardly find so large a reading public here as it apparently does in Germany. Even unbound it costs 16*s*. It deals with five subjects which have not much in common. It touches things aerial and things terrestrial.

Privat-docent Dr. A. Wegener, of Marburg, in about 70 pages deals with the recent results obtained in what is a new and vigorous department of meteorology—a department that had its genesis only 20 years ago, but is now a substantial section of meteorology, and is dignified by the name of aerology. The modern methods used for obtaining a knowledge of the condition of the higher atmosphere, such as the varieties of balloons and kites which are in use, are described and illustrated. The temperature, moisture, and other conditions of the upper air are described, cloudland is studied and illustrated, and the whole problem of the physics of the upper atmosphere is fully discussed. Some of the views of clouds as photographed from cloudland are excellent. Next W. Johannsen, of Copenhagen, gives in about 65 pages a very circumstantial account of recent experiments in relation to heredity, including details of his own work on pure strains of beans and other plants. The work of Galton, of Karl Pearson, and others, is passed in review and criticised, and so is that of Darwin. Mendel's work is dwelt on and its importance in relation to the Darwinian hypothesis is pointed out. The zoological aspect of the question is illustrated by observations made on certain forms of water fleas, such as hyalodaphnia. It is impossible to summarise the author's views in a few lines, so that we must refer the reader, and especially the botanical reader, to this highly interesting and technical account of the problems of heredity. The zoologists also will be interested in the results obtained by crossing examples of the obstetric toad (Alytes)—results which can now be explained on Mendelian principles.

About 80 pages are devoted to the history, evolution, and present position of wireless telegraphy and telephony, by G. Eichhorn, of Zürich. This again is an interesting and very technical subject. M. Rikli, of Zürich, deals with the geographical distribution of plants, and remarks that though herbaria were collected, labelled, and described long ago, and the utilitarian aspects of plant life were studied, the geographical distribution of plants is only a comparatively recent subject of scientific investigation. Its founder was Alexander Humboldt (1769–1859), who published his "Essai sur la Géographe des Plantes" in 1805–06. M. Rikli's interesting essay deals with such subjects as heat, moisture, light, wind, condition of soil, and so forth, as they influence plant life over the globe. It gives an excellent summary of the subject dealt with.

Professor H. Klaatsch, of Breslau, promises a series of articles on the origin and transmission of special human characteristics, and in a short paper begins his contributions with "The Story of the Hand." Going back to the geological record to the study of fore-foot prints in the primary and secondary rocks, he begins with the footprints of Cheirotherium, and proceeds to trace the evolution of the human hand from the point of view of the comparative anatomist. Where is Paley's doctrine? The treatise on the hand by Sir Charles Bell will still continue to charm the reader, if such there be in these days. Man is the only primate which has retained the thumb in its complete development. The gorilla in this regard comes close to him, but here the thumb has undergone a relative shortening. This is a most interesting and suggestive communication.

To each of the papers is appended an excellent bibliography.

Modern Methods of Sewage Purification. By G. BERTRAM KERSHAW. With tables, illustrations in the text, and 36 plates. London: Charles Griffin and Company, Limited. 1911. Pp. 356. Price 21*s*. net.

THE attitude which the author adopts in regard to the great problem of sewage purification and disposal will be endorsed by all those who realise the peculiar difficulties of the subject. As he says, "Sewage treatment does not lend itself to patents," by which he means that there can be no best method of sewage disposal which can be universally adopted regardless of local conditions. Innumerable and valuable patents there have been and are, however, which of course have helped in the stages of general methods, but "there are many methods, each one of them good in its own particular way, when properly designed and when suited to the local circumstances." It is exactly these "local circumstances" that keep one sewage method short of universal application and that add to the complexity and perplexity of all problems connected with the treatment and disposal of sewage.

What Mr. Kershaw has to say will be listened to with every attention, because he has been in close practical contact with the many and varied phases of the subject for several years, and his views have been made more authoritative by his connexion for 12 years as engineer with the Royal Commission on Sewage Disposal. The work of that body has been extremely valuable, and when completed will remain a source of reference on the subject which can have no rival for a very long time. In the present volume the subject is approached chiefly from the engineering point of view. Mr. Kershaw refers his reader to the special books upon the question of the chemical and bacteriological purification of sewage, and after a most interesting chapter on the history of sewage treatment he proceeds to describe some of the more efficient methods of sewage disposal in use at the present day, while discussing at some length the practical and financial points which require consideration. He misses no detail in his account of the various processes described, and a valuable feature of the work is the emphasis he gives to his words when he is discussing points which he holds from experience to be essential to success. Valuable, also, are the references to adaptability of various schemes to different places, examples being given in the chapter on "Purification Works in Actual Operation." The chapter on trade wastes brings out the difficulties which the sewages of industry present in regard to effectual treatment, and shows how these difficulties have so far been dealt with. His suggestion in a miscellaneous chapter of the desirability of a central authority being created, which should be able to make an investigation, when it is required, for several authorities or manufacturers, at the expense of the authority and not at that of the ratepayers of the particular town or of the manufacturer, is to the point, and worth careful consideration. As he says, "At present one of the greatest stumbling blocks to progress in the purification of sewage and manufacturers' wastes is lack of knowledge. The local authority or manufacturer, as the case may be, is told, 'You must discontinue this pollution,' frequently without any intimation of the direction in which the remedy is to be sought.

The central authority should point the way out and bring about a decisive and satisfactory issue.

The book is sure to be favourably received by all those interested in the advances of this most important branch of sanitary science.

Clinical Immunity and Sero-Diagnosis. By A. WOLFF-EISNER, M.D. Berlin. Translated by RAY W. MATSON, M.D., Professor of Histology, North Pacific College of Dentistry and Pharmacy, &c. London: Baillière, Tindall, and Cox. 1911. Pp. 184. Price 7*s.* 6*d.* net.

THE author records in the preface to this work that it is intended to "establish a connexion, previously lacking, between biology ..... on the one hand, and the clinic (particularly general practice) on the other." He states that his "venture was unprecedented," meaning apparently that there was previously no book available in Germany which set forth the theory of immunity in easily intelligible language. In our own country several books of this nature have been available for some years. Nevertheless, we welcome the translation of Dr. Wolff-Eisner's book, as it contains much of interest. Its principal thesis is the attempt to explain the phenomena of infection and immunity in terms of the discovery that a foreign albuminous substance brought into contact with the cells of a living body gives rise to the production of lytic substances, which tend to break it up. The symptoms of bacterial infection are thus attributed to the action of the body-substance of the organisms which are broken up by bacteriolysis, and we are introduced to the apparently paradoxical view that it is only by the death of the bacteria that the sickness and possible death of the host are caused. The crisis of an infective disease is due to sudden bacteriolysis, since a large dose of the toxic substance produces a fall of temperature, whereas a small dose gives rise to fever. (But why should the destruction occur suddenly and not in gradually increasing amount as the lysins are generated?) Similarly the exanthem of an infective fever is due to freeing of toxic albumin by lysis of bacteria, and the action of tuberculin is explained as due to the introduction of an antigen in presence of the lysin capable of disintegrating it with formation of toxic derivatives. Other diseases capable of explanation on the same lines are asthma and urticaria, in both of which the symptoms are due to the action of poisonous albuminoids on the vasomotor system; also eclampsia, which is associated with absorption of placental villi and resulting anaphylaxis. The author throughout sets forth his own views rather than those generally accepted; indeed, he quotes his own published works to an extent which becomes somewhat tiresome. It is possible that he attributes to his own observations greater importance than is generally admitted, and wishes to correct a possible lack of appreciation.

The book may be read with interest and advantage by those who are familiar with the subject of immunity and who can correct one-sided statements with the necessary pinch of salt. The author's views are fresh and stimulating; time alone can show the exact degree of truth underlying them.

Handbook of Electro-therapeutics. By WILLIAM JAMES DUGAN, M.D., Lecturer on Electro-therapeutics at Jefferson Medical College, &c. Philadelphia: F. A. Davis Co. Pp. 242. Price 8*s.* 6*d.* net.

THIS should prove a useful handbook, seeing that it occupies a place more or less midway between the large work which most medical men find too long to read and the small one that is intended more for the use of students. The author has carried prudence very far in that he has confined himself to so much of the subject as we can be reasonably sure of, and has carefully avoided touching on the more debateable points.

As the book is intended primarily for those who know little or nothing of electricity, the preliminary chapters are given up to more or less elementary principles and considerations. Chapter III., on static electricity, is one of the best in the book, though the difficulties attendant upon the use of static machines in a climate such as ours deprives it of practical interest to many of our readers. Subsequent chapters treat very clearly of faradic currents, electrical testing, electrolysis, and cataphoresis, though we think the author should have gone more fully into the latter subject, considering the great advances that have been made in this direction in recent years.

With regard to the application of high-frequency currents, the author does not hold out undue encouragement, and while he gives directions for their use in several specific conditions, he adds little reason to think that any great good will result, and in many of these conditions he is careful to say that medical treatment should also be employed. He has, however, found the method of great use in acne, nasal catarrh, insomnia, and some forms of neuritis. Towards the end of the book there are short chapters on magnetism, or rather treatment by means of magnetic waves, and also on light and heat therapy. The work closes with a comparatively full dissertation on the advantages of electrocution over hanging in dealing out the death penalty.

The book is very fully illustrated, but the author might have used more original illustrations and fewer illustrations derived from the electro-medical instrument manufacturer. Further, the reason for introducing illustrations of X ray apparatus and radiographs is not quite obvious, seeing that the subject of the X rays is scarcely referred to in the text. The radiographs are of very indifferent quality, and why they should be described as "Campbell radiograph of elbow," "Campbell radiograph of hand," and so on is not apparent. Of the series, Fig. 70, an antero-posterior view of the ankle, is described as "Campbell radiograph of wrist"! These pictures should be deleted in future editions, and no doubt other small defects will then be rectified. The main idea of the book is good, and on the whole it has been well carried out. For these reasons we have no hesitation in recommending it to those who are inclined to take up this branch of medical work. None the less some revision would be salutary.

LIBRARY TABLE.

Common-Sense Dietetics. By C. LOUIS LEIPOLDT, F.R.C.S. Eng. London: Williams and Norgate. 1911. Pp. 243. Price 2*s.* 6*d.* net.—Within the limits of a handy volume Mr. Leipoldt has brought together all that the ordinary man needs to know on this subject, which he has dealt with not so much from the professional or scientific standpoint as from that of the intelligent layman who wants to know the reason for this, that, and the other dictum in dietetics. It will also be of interest to the gourmet, who will here find rational explanation for many culinary practices and prandial rites and customs. An outline is given of the general principles of dietetics and the physiology of digestion; also of the composition of foodstuffs and the methods of their preparation. Dietetic fads and fallacies and the true art of dining are treated of with expert knowledge and sound sense. In the table of standard diets we notice an omission of any British scale more recent than Playfair's. The statement (p. 20) that the large intestine is "merely a reservoir," implying that it has no important digestive function, is hardly in accordance with the teaching of the present day. The author properly distinguishes between the *gourmand* and the *gourmet*, and introduces us to the "gastrosoph, the dietetic artist, the expert who knows how to eat, when to eat, and what to eat." As to alcohol, he is far from being a prohibitionist, and is,

indeed, fully alive to the attractions of good wine, but he prefers to say that alcohol taken in moderation at meals is "not detrimental" rather than to assert that it is "a distinct help" to digestion (p. 38). He is no vegetarian, believing that a purely vegetable diet is not desirable for anyone who, as Thomas Walker, of *The Original*, said, "knows how to dine so as to preserve the maximum enjoyment with the greatest advantage to health." But the use of fruit should be much more extensive than it is, and we believe many busy men would be the better for taking Mr. Leipoldt's "ideal summer lunch" of a bunch of Malaga raisins and a tumbler of milk instead of the ham sandwich and glass of beer or the solid midday meal. The author is against all fads, whether those of vegetarians, fruitarians, or others. Brain-workers, he finds, do not require a large amount of phosphorus in their diet; concentrated or predigested foods are not more nutritive than ordinary articles well prepared; neither does he believe in the value of a purin-free dietary or of "standard" bread; a middle position is taken as regards alcohol, the author's inference being that alcohol, taken in small quantities, is a valuable dietetic aid, but no more a food than a tablespoonful of jelly is, yet as much a food-sparer as the latter, and with a definite place in the dietary. This appears to be the author's considered opinion rather than the contrary statement on p. 38. Mr. Leipoldt has not always verified his references. Johnson is quoted as saying that "the drink for heroes is whisky"; what the sage did say was, "No, sir, claret is the liquor for boys; port for men; but he who aspires to be a hero must drink brandy." In the chapter on the Art of Dining the author presents several specimen menus for our instruction. He quotes Walker's "ideal dinner for a party of eight on Christmas Day" as turtle soup, whitebait, grouse, apple fritters and jelly, ices. Whitebait Mr. Leipoldt condemns because it is not at its best in December; but Walker ordered the dinner "this very day at Lovegrove's, at Blackwall, where, if you have never dined, so much the worse for you," and the date was August 26th, 1835 (see *The Original*, No. XV.). Despite a slip or two we are grateful to the author for good advice on the art of dining and information about famous diners. The "note" of the book, as indicated in the title, is common sense.

Through India and Burmah with Pen and Brush. By A. HUGH FISHER. London: T. Werner Laurie. Pp. 358. Price 15*s.* net.—Mr. Fisher has been about the world a good deal, and is able to recount his experiences in a pleasing fashion without any fine writing. He first went to Burmah, and ascended the Irrawaddy as far as Bhamo. He gives a good description of the deserted ancient city of Pagan, which he calls the "Dead Heart of a Kingdom." After a flying visit to Madras and the South of India he went to Calcutta. The description of the visit to the Hindu theatre is amusing. Few Europeans interest themselves in the Beadon-square neighbourhood, or in Bengali theatrical entertainments. After Darjiling, Benares, Lucknow, and Cawnpore, Mr. Fisher went to Fatehpur Sikri. This wonderful dead city does not seem to have made any great impression, and we are not given a single picture, plain or coloured, of its many architectural features; not even of that magnificent Buland Darwaza, or Sublime Porte, 160 feet high, surely the greatest gateway in the world. Mr. Fisher then continued his journey up country from Agra, through Delhi, Amritsar, and Lahore to Peshawar, afterwards visiting Quetta, Jaipur, and Udaipur. We should have liked to learn what were the most vivid impressions the artist-author carried away with him from his rapid but comprehensive survey. Perhaps it was too kaleidoscopic. The coloured reproductions of his painted sketches are particularly successful, and give an excellent idea of the vivid hues and sharpness of outline characteristic of tropical landscapes. Rohri and Sukkur are hot enough, but the engineer must have been "pulling the artist's leg" when he assured him that the thermometer reached 240° F. in the shade at either of those places (p. 281). No such shade temperature has ever been recorded in India. Mr. Fisher concludes with the expression of his opinion, in regard to the future of India, that a distinction must be made between the extreme claims of enthusiasts and the reasonable progressive changes warranted by a gradual advance of education and increase in religious tolerance, as well as between the irritation of dissatisfied place-hunters and the mature opinions of enlightened Indians in positions of trust and authority. Lastly, in its efforts to make a nation out of a tangle of many States and peoples, England must never forget the tremendous power it has gradually gained to influence the liberty and progress of the world, and that "no part of that power can ever be yielded up, save as the shameful shifting of a burden it is our noblest privilege to bear." This is a weighed and judicious expression of opinion which will commend itself to careful and discriminating thinkers. The author seems to us to lapse from good taste in his anecdote on p. 213.

Modern Medical Opinions on Alcohol. Being a Series of Lectures delivered by well-known Medical Men. London: Church of England Temperance Society. Price 1*s.* Pp. 129.—This little book is a collection of 14 short papers and addresses by well-known members of the profession on the physiological and pathological effects of alcohol. Sir Frederick Treves introduces the subject. Sir Thomas Barlow speaks of intemperance among women. Sir James Crichton-Browne advises students who aim at efficiency to place every form of alcohol on their *index expurgatorius*. Sir Victor Horsley maintains that "alcohol depresses the vital activity of the human body, and therefore cannot possibly be regarded as a food." A very good and practical address is that of Dr. Ettie Sayer on the Prevention and Cure of Intemperance, as is one by the late Dr. George Carpenter on Alcohol and Children. The manual is free from exaggeration, and would be of great use to anyone desirous of informing himself of the views of leading physicians on this subject.

The Bellevue Hospital Nomenclature of Diseases and Conditions, with Rules for the Recording and Filing of Histories. Compiled by the Committee on Clinical Records, composed of ROBERT J. CARLISLE, M.D., WARREN COLEMAN, M.D., THOMAS A. SMITH, M D., and EDMUND L. DOW. Adopted by the Board of Trustees, 1903. Revised and made to Conform to the International Classification, 1911. Copyright, 1911, by the Board of Trustees of Bellevue and Allied Hospitals, New York. Pp. 323.—This small book presents the nomenclature of disease employed by the Bellevue Hospital, New York, for recording and filing the records of its cases. It has been designed for convenience of storing records, making references, and acquiring mortality and morbidity statistics. The present edition represents the third revision of the nomenclature, and it has been brought into accord with the international list of causes of death by prefixing to each of its terms the proper international title-number. The general principles of the system of records adopted by the Bellevue Hospital authorities are first explained. The directions given appear to be admirably systematic and calculated, if efficiently followed, to yield valuable material for statistical investigations. The nomenclature itself is first expressed according to the system or organ diseased or injured, the individual conditions being arranged in alphabetical order; then we have the order under the titles of the international classification. An alphabetical index is then given. In this way the names of the individual conditions are given in three different categories, and reference to any given

disease or injury and the determination of its position in the classification are facilitated. The orthography is stated to conform to that recommended by the Basle Anatomical Nomenclature and is endorsed by the Committee on Nomenclature of the American Medical Association. For the most part it is identical with that current in this country, though "septichæmia" has an unfamiliar appearance and enforces a new pronunciation. We are glad to find that proper names appended to diseases are but little used, the only examples we have found being Mikulicz's disease, Hodgkin's disease, Morvan's disease, and Werlhof's disease. The book is well produced, is of convenient size, and offers a practical and carefully-worked-out scheme of nomenclature and classification which should be useful if generally adopted in the collection of records in hospital or private practice.

JOURNALS AND MAGAZINES.

Man.—In the December number of this journal Dr. Jos. Maes, keeper of the ethnographic section of the Congo Museum in Belgium, contributes an account in French of a collection made by Dr. Mordiglia. These objects belonged to a *fétiche*ur, and most of them were naturally supposed to possess magical powers; besides these there were several intended for use in the treatment of diseases and injuries, including samples of native medicines; several boxes or cases for holding medicines and surgical instruments; a calabash used as a cupping instrument, in which the *fétiche*ur produced a partial vacuum by sucking with his mouth; another calabash filled with fluid and fitted with a nozzle for introduction into the bowel, after which the *fétiche*ur administered an enema by blowing into another aperture in the gourd; a splint for fractures, made of parallel strips of bamboo laced together with vegetable fibres; a sharp iron instrument for bleeding and tattooing; slips of quartz shaped for filling the teeth; and a notched iron instrument which could be used either for breaking off portions of a tooth or for an extraction.

School Hygiene: A Monthly Review for Educationists and Doctors. London: Magazine and Publication Syndicate, Limited. Price 6*d.*—This magazine will in future appear as a quarterly journal, and will no doubt maintain the high standard of interest its articles have always had for the growing number of men and women—doctors and others—connected with, and interested in, the health sides of school life. The November number contains, among other things, the conclusion of a paper by Dr. F. C. Shrubsall on the examination of Mentally Defective Children, which should prove of great practical assistance to doctors and teachers alike. The December number has an elaborate and interesting paper on Poliomyelitis in Relation to the Spread of Infection by Schools by Dr. F. E. Batten, and a discussion on this paper by the Medical Officers of Schools Association. Miss A. C. Sewell has a stimulating article on How to Use School Playgrounds, in which she gives some of the results of her splendid work in this field.

ROYAL LONDON OPHTHALMIC HOSPITAL.—The sixth annual dinner of the past and present students of this hospital will take place at the Imperial Restaurant, Regent-street, London, W., on Wednesday, Feb. 7th, at 7.45 for 8 o'clock. Mr. F. Richardson Cross will take the chair. Each student is entitled to introduce two guests. Tickets (price 10*s.* 6*d.* each, exclusive of wine) may be had on application to either of the honorary secretaries, Mr. Arnold Lawson, 12, Harley-street, London, W., and Mr. J. Herbert Parsons, 54, Queen Anne-street, London, W.

Reports and Analytical Records
FROM
THE LANCET LABORATORY.

REAGENTS FOR USE IN THE WASSERMANN SYPHILIS REACTION.

(A. AND M. ZIMMERMANN, 3, LLOYD'S-AVENUE, LONDON, E.C.)

WE have received from the above firm specimens of the reagents used in the Wassermann reaction which are prepared under the supervision of Professor Wassermann himself and independently examined by Dr. Meier. The reagents represent the same as those used by Professor Wassermann in his own clinic. The series sent to us comprised 1 cubic centimetre of hæmolytic amboceptor, 1 tube (5 sera) antigen (alcoholic extract of syphilitic liver), 1 positive standard serum, 1 negative standard serum, 1 envelope hæmolytic amboceptor, and 7 cubic centimetres sheep's blood corpuscles. Instructions for use are issued from the bacteriological and serological department of the Pharmaceutical Institute of Ludwig Wilhelm Gans, Frankfort-on-the-Main.

(1) IODOSTEM; AND (2) STEM.

(R. LANE HALL AND CO., 4, LLOYD'S-AVENUE, LONDON, E.C.)

Iodostem is a thick syrupy fluid obtained by the concentration of grape juice. It contains iodine combined loosely with tannin, so that the iodine is available for administrative purposes without the disagreeable effects of iodine in the free state. It has been employed in disorders of the lymphatic glands as well as in gout, rheumatism, and tubercular affections. Stem itself is a clear pure grape juice, a pleasant slightly acid liquid which forms an agreeable beverage when diluted with either plain or aerated water. On analysis the following results were obtained: Total solid matters, 18 65 per cent.; grape sugar, 15·20 per cent.; acidity reckoned as tartaric acid, 0·45 per cent.; and salts, 0·30 per cent. We could find no preservatives, while the iodoform test showed almost complete absence of alcohol.

GENUINE HOLLANDS (DE KUYPER'S).

(JOHN DE KUYPER AND SON, ROTTERDAM. LONDON AGENCY: 6 AND 7, GREAT TOWER-STREET, E.C.)

This spirit bears all the evidence of a correct description. It is stated to be distilled from genuine malt liquor with the juniper berry, the oil of which contributes to some extent to the peculiar flavour. There is an advantage undoubtedly gained by distilling the berry with the spirit; the resulting product is mellow and free from harsh flavour. A simpler method, of course, is to add the oil. On analysis the spirit gave the following results: Alcohol by volume, 47·13 per cent.; proof spirit, 82·59 per cent.; extractives, *nil;* mineral matter, *nil;* and volatile acid reckoned as acetic acid, 0·012 per cent. The secondary products in parts per 100,000 of alcohol present were as follows: Aldehyde, 8 parts; furfural, 9·3 parts; ethers, 67 parts; and higher alcohols 237 parts. The amounts of secondary products show that the spirit is produced in the classic pot-still, so that the volatile flavours of the materials are retained. On extracting the spirit with petroleum ether a definite quantity of juniper oil was obtained. It will be remembered that juniperi oleum is official in the British Pharmacopœia and is described as carminative, anti-spasmodic, and a stimulating diuretic, the last-named property constituting its chief medicinal value. In some text-books it is mentioned that juniper is conveniently given in the form of hollands or gin. De Kuyper's hollands is still made after a formula which is over 200 years old, and our analysis establishes the genuineness of the product.

NOVOFORM (HAYDEN).

(AGENCY, E. W. BLASIUS, 127, FENCHURCH-STREET, LONDON, E.C.)

Novoform is introduced as a new odourless antiseptic. We have examined a specimen, and find that it is a fine dull yellow powder quite free from smell and insoluble in water. It is a combination of bismuth oxide with tetra-pyro-catechin, an aromatic antiseptic containing bromine. We had no difficulty in expelling bromine from the compound or in identifying the presence of bismuth. Its important properties are that it is antiseptic and exsiccative, and is valuable, therefore, in suppressing or preventing suppuration. It is said to be non-poisonous, and is apparently an excellent substitute for iodoform for the reasons just stated.

VARIOUS BOTTLED FRUITS.

(D. E. TOWER, F.R.H.S., THE HILL FRUIT GARDENS, PERSHORE.)

The excellence of these preserved fruits shows that the simple process adopted is a success both from an æsthetic and a hygienic point of view. No time is lost in consigning the picked fruit, which has been selected as sound, to the bottle. There is thus very little opportunity of contamination or undesirable fermentative changes. The soft fruits are bottled direct from the trees or bushes; after bottling they are carefully pasteurised and then they keep (according to the excellent samples we received) in good condition. The natural colour is also preserved. The raspberries were particularly attractive in this direction. We could find no trace of metal or of chemical antiseptics.

SCOTCH WHISKY (THE HUNTING SQUIRE BRAND).

(WALTER BALLANTYNE AND SON, ST. BOSWELLS, SCOTLAND.)

The mellowness that comes from storage is a characteristic of this spirit. According to our analysis it is a blend, but possesses a marked flavour of malt. The results of analysis were as follows: Alcohol by volume, 44·78 per cent.; extractives, 0·230 per cent.; mineral matter, 0·01 per cent.; volatile acidity reckoned as acetic acid, 0·018 per cent.; and fixed acidity reckoned as tartaric acid, 0·015 per cent. The extractives are a little higher than is generally the case, owing, doubtless, to maturing in wood. The secondary products in parts per 100,000 of absolute alcohol were as follows: Aldehyde, 11·40; furfural, 1·13; ethers, 51; and higher alcohols, 140. When whisky is permissible for dietetic purposes a spirit of this smooth mature character is an advantage.

(1) FERROSAJODIN; AND (2) TUBERCULIN A. F. (ALBUMOSE-FREE TUBERCULIN).

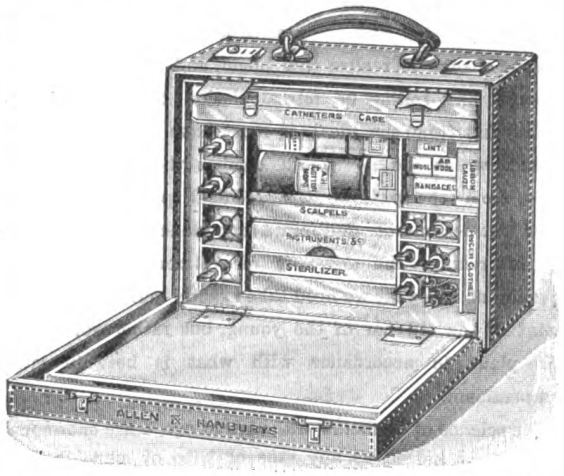
(MEISTER LUCIUS AND BRÜNING, LIMITED, 3, JEWRY-STREET, LONDON, E.C.)

1. Ferrosajodin is regarded as an advance upon syrupus ferri iodidi, inasmuch as both the iron and iodine in it are exhibited in forms which do not give rise to the objectionable disturbances common to ordinary iron and iodine compounds. Ferrosajodin is tasteless; it is without discolouring effect upon the teeth; is free from irritating effects upon the digestive tract, and keeps unaltered or unoxidised when exposed to the air. We have examined some chocolate tablets containing the compound. Ferrosajodin contains about 5·6 per cent. of iron and 25 per cent. of iodine. The iodine, we found, is readily expelled on treatment with nitric acid. Sajodin is the calcium salt of mono-iodobehenic acid (iodo-sebacic acid) and was described in our analytical columns in THE LANCET, May 5th, 1906. Its combination with iron suggests its useful application in the treatment of scrofula, chlorosis, anæmia, and cachectic conditions, and good results have been reported. 2. Tuberculin A.F. is prepared from the bacilli cultivated in a special nutrient medium consisting of inorganic salts and citrates, the sole nitrogenous food present being asparagin. There is no addition of albumose, peptone, or nitrogenous extractive matters derived from flesh or blood. It is stated that the advantage of Tuberculin A.F. over the older Koch's preparation consists in the strictly specific character of the reactions induced by it, and that anaphylactic symptoms are excluded in consequence of the absence of non-specific proteins. It may be used for both diagnostic and therapeutical purposes. We found that bromine water gave an opalescence but no precipitate. Alcohol did much the same thing, while when the fluid was saturated with zinc sulphate it remained clear. These results prove the absence of peptones and albumoses, as is claimed to be the case.

New Inventions.

ASEPTIC DRESSING CASE.

THE appended sketch displays a surgical dressing bag which will appeal to the majority of busy practitioners on account of its carrying capacity and general utility. It is evolved from the brief bag, into which instruments and dressings are often thrown at haphazard, but which has proved quite inadequate in these times when the principles of asepsis are understood by our patients no less than by ourselves. Use has proved it efficient; it enables the surgeon to dress cases or to perform minor operations aseptically. Essentially a metal case, for convenience carried in a leather attaché case, it is divided into compartments for bottles, dressings, and instruments, viz.: Four 3 oz. bottles for ether soap, lysol, sp. vini rect., lotio plumbi cum opio; five 2 oz. bottles for ac. carbolic, antiseptic cream, vaseline,



powder, and so forth; stoppered tubes for suppositories, tablets, adrenalin, argyrol (six of these occupying the space of one 2 oz. bottle); compressed dressings, bandages, at one side a narrow space for finger cloths; steriliser, 8 in. by 4 in. by 2 in. of usual pattern; metal box 8 in. by 4 in. by 2 in., holding instruments, needle box, tube of ligatures and sutures; and catheters, uterine and other long instruments in a case, 13½ in. by 3½ in. by 1 in., running the whole length of the bag. There is room in the central part of the bag for vaginal specula, battery, and head light, or extra dressings.

Messrs. Allen and Hanburys, Limited, of 48, Wigmore-street, London, W., have taken considerable trouble in making this case exactly to my instructions.

Folkestone. W. W. LINNGTON, F.R.C.S. Eng.

THE LANCET.

LONDON: SATURDAY, JANUARY 6, 1912.

A Nonagenarian.

DURING 1912 THE LANCET will enter upon the ninetieth year of its existence, and the temptation is strong upon us to suggest that we should not have lived thus long if we had not lived fairly well. Perhaps if we felt old some garrulous reflection upon bygone efforts would escape us at this date, though struggling to preserve modesty. But we have no sense of the weight of years. To the young the New Year is essentially a period of resolution, hope, and promise, and we are more in touch with this attitude. A newspaper which represents the vital interests of a progressive profession, so long as it represents them truly, can neither be called old nor young; whatever its actual years, it is the age of that profession, whose past it has to reckon with, whose present it lives by recording, and whose future it strives to assist. "Si la jeunesse savait, si la vieillesse pouvait," that most used tag by all who write, suggests the impossibility of attainment in human affairs to any working blend of youth and experience. A newspaper, which is itself part and parcel of a living and progressive section of human energy, has the chance to realise this blend, and however far short through any frailty or miscalculation of its conductors it may fall from the ideal, it must have as many circumstances which aid as which combat the ambitious aim. Thus from the past of the medical profession we can draw the lessons of deliberate experience, and from the present receive the messages of valorous hope. At the opening of this year we need take exactly neither the standpoint of the old nor of the young, but rather would make our plans in accordance with what is best in either temperament.

The science of medicine, although in one sense enormously old—as old indeed as any race or tribe of man—is not a very ancient branch of human achievement as we know it. Where the records of civilisation extend back we find always traces of definite and accurate medical learning, and some of these traces indicate extraordinary intellectual acumen on the part of those original votaries of our science. But the skill of this or that nation in this or that pathological direction was largely lost as a benefit to the world by the absence of common principles and the instability of basic knowledge. In the result, as all our readers know, the systems of ancient medicine stood still at certain points, and during many hundreds of years no man could say that general progress of any kind had been made. There was little continuity of attempt and almost no consensus of design, so that either by independent labour or by rediscovery of buried lore the nations of the earth arrived, and arrived again after vast intervals of time, at much the same station in the course. Then, and in comparatively recent days, great physical and physiological truths threw a light upon the learning of the past, revealing some of the most ancient procedures as justified by science, and exposing others, perhaps more venerated, as vestiges of vulgar superstition. The good has been kept and the falsehood has been rejected, and to such parts of the older learning as would stand the severe tests of real science vast stores of information have been added under the improved conditions. Partly by the insight of a few leaders has this been done; partly by the faithful work emanating from the body of medicine as a whole; and partly by the growing wisdom of the world, which, returning in a practical form to philosophic dreams, has begun to realise in the interaction of various branches of knowledge that there is not one wisdom of the chemist, another of the botanist, and another of the pathologist, but that the wisdom of all is one. The principal advances of medicine lately have been due to the fact that provinces near to the medical borders, which seemed to be required by the medical estate, have been assimilated, and that medicine has learned to rule them and has thriven out of their produce. Now much of such development of medicine has taken place within the life of THE LANCET, and during the whole period we have attempted to describe the actions of the leaders, to mirror the good work of the rank and file, whose general experience is sublimated into the essential quality of their leaders' exploits, and especially to chronicle the growth of medicine as an acquisitive science, making magnificent raids upon territories apparently allocated to other possessors, and retaining peaceful possession of the conquests. We can look back upon such labours from a respectable position of maturity, but we prefer to look forward to the countless opportunities that are unrolling themselves in which we may serve medicine in a similar manner through its majestic developments.

And as we have tried to record the scientific progress of medicine, so we have tried to record the position of those who practise it, their professional needs and aims. At this moment in the material history of the profession of medicine there is the greatest need—never has there been greater—for looking facts squarely in the face and for seeing that the action taken upon those facts shall be taken for the national good by a highly educated class, which is always forced by circumstances, as well as guided by disposition, towards altruistic endeavour. If this class is to discharge its high responsibility in accordance with the conception which it has always had of its duties, it must undergo a long, arduous, and expensive training, and, again, must have proper opportunities accorded to it for carrying on work whose routine is arduous, delicate, and complicated. It will be our duty in the struggle which seems imminent to keep the attention of our readers fixed upon the principles involved, to resist in their name social and political movements which threaten the scientific and material position of those who practise medicine, and to support the extending movement of the medical profession towards a common demand for justice.

Optimism in Medical Practice.

"I HAVE always observed," wrote the late Sir WILLIAM HARCOURT, "that good physicians are optimists," and the observation is at least equally applicable to good surgeons, no distinction probably having been intended. We do not use the word, nor presumably did Sir WILLIAM HARCOURT, in its philosophical sense, as indicative of a follower of LEIBNITZ, or even of POPE'S travesty of his doctrines, rather than of SCHOPENHAUER or of HARTMANN, but in the more obvious one which indicates a person whose disposition it is to hope for and expect the best, or to look on the bright side of things rather than on its reverse. We are all familiar, in daily life, with the wholesomely stimulating effect of the optimistic point of view; and, even granting that it may sometimes, or even often, lead only to disappointment, most people will clearly be the better for the effort which it induces them to put forth, and will be more capable of "trying again" when next the opportunity is afforded them. In the sick room, the optimism of the physician or the surgeon, as expressed in countenance and manner, conveys to the patient that most comforting of all assurances—the assurance that he is not merely to be looked at, but that something is about to be *done*, and that presently, for his relief; that there is to be no passive acquiescence in his suffering or his danger, but a well-directed effort to restore him to comfort and safety. To such an assurance, springing less from words than from a certain vigilant and ready manner which is more easily recognised than described, the patient will almost certainly respond by an increase of hopefulness which in itself is a wholesolme stimulant to any powers of recovery which he may possess; and few who are conversant with sick rooms will entertain any doubt of the frequent efficacy of conditions which appeal to favourable expectation and tend to the maintenance of, at least, comparative cheerfulness. To the practitioner himself, whether medical or surgical, the reasonably optimistic frame of mind is almost as valuable, from the point of view of his efficiency, as it is to the patient; because it at once directs his thoughts to practical issues, and diverts him from the contemplation of the urgency of danger by demanding all his energies for the devising of means by which that danger may be averted. The man whose first and instinctive impulse is to act, and to act with promptitude, will always, other things being equal, be more successful than he whose first impulse is to fear that his activity may only be in vain; and even in the worst conditions, when the hope of success is almost absent, the encouragement of that which may remain will be an essential aid towards the fulfilment of one of the first duties of the practitioner—to remain calm in the presence of adversity. How many cases of apparent death from drowning, for example, have been restored to life by men whose optimism has led them to persevere in effort even when it appeared that all hope must be abandoned?

There are, however, two distinct kinds of optimism to be considered, the optimism of the energetic and the optimism of the idle; and the latter is even more certain to be disastrous than the former is to be beneficial. The optimism of the energetic leads to the practical conclusion that the patient may be cured, or may recover, on the condition that every possible chance is given to him, and that nothing conducive to his restoration is forgotten or omitted. In such circumstances optimism is merely the recognition of what may be accomplished if the most favourable external conditions are maintained; and its practical outcome should be a determination to maintain them. The possibility of doing so will depend, obviously, in many cases, upon conditions over which the practitioner can exert but a limited degree of control; and his success will be largely governed by his power to assert his influence in the sick-room, and to compel attention to even the most apparently trivial of his directions. As regards patients in comfortable worldly circumstances this power has been enormously increased during recent years by the development of skilled nursing; and there can be no doubt that the results of treatment have in a corresponding degree become more successful. Even with the aid of this most valuable adjunct, the physician or surgeon who is optimistic in the favourable sense will not allow his vigilance concerning details to be relaxed, more especially in the many cases, occurring in middle-class houses, where the nursing strength is hardly adequate to the requirements of the patient, and is reinforced by members of the family or by friendly amateurs. We once knew a country practitioner who ascribed much of his undoubted success in serious cases of illness to his habit of paying surprise visits to them at all hours of the night or early morning, and of thus learning from direct observation how far the conditions which he had prescribed had been fulfilled. He was an optimist of the first order, always cheerful, always hopeful so long as hope was possible, but fully recognising the necessity of means for the fulfilment of ends, and resolute, so far as his power of controlling events extended, that the means should be there, and should be applied in accordance with his directions. It is in this form, and perhaps in this form only, that optimism in the sick room is to be unreservedly commended. It must be guided by a realisation of one of the first results of modern scientific inquiry—of the fact, that is, that no condition capable of adversely modifying the chances of the sick is so small that it can safely be regarded as trivial. It is only when this knowledge is fully acted upon that room is afforded for the true foundation of medical or surgical optimism, which is based on another fact, that is, that only a few diseased conditions, save towards the natural decline of life, are so necessarily fatal as to exclude the hope of dealing with them successfully.

The optimism of the idle, even assuming them to be only intellectually idle, is a quality of quite a different order, and is necessarily productive of very different consequences. It is founded upon an implied belief that everything is for the best in this best of all possible worlds, and that affairs in general will come round if they are left alone. When expressed in guarded language by medical men, it is not infrequently made the foundation of wholly erroneous ideas on the part of the public; and it is usually associated with very convenient lapses of memory concerning facts calculated to shake its very foundations. Even lately it has led some people to believe that a mere period of residence in a sanatorium would "cure" most cases of pulmonary

phthisis, and that the uncured patients who came out would at once commence the diligent practice of troublesome precautions for the protection of those around them. Laziness and selfishness and dirty habits were to be cured, even when the phthisis itself resisted treatment. In the domain of surgery the optimism of the idle tends to the conclusion that this or that "will do," and hence to the neglect of the small precautions on which, in so many instances, success is dependent; while in an analogous fashion it invalidates the results obtained from a large number of so-called observations of various kinds of phenomena. In its relations to the general public it is perhaps in no way more hurtful than in its tendency to lead to hasty or mistaken diagnosis, to the belief that things are always what they seem, and that first impressions may be continuously trusted without revision or re-examination. In a word, it is the antithesis of caution, and caution is the essential condition of the ascertainment of truth, and of its detachment from the many errors which may lurk under its disguise. As FARADAY long ago pointed out, it is necessary to know all the conditions under which phenomena occur before it is possible to form a sound judgment of their nature or of the causes producing them; and the intellectually idle optimist is one who neglects this precaution, and who announces a conclusion based upon his knowledge of some of the conditions only. Such a conclusion, for example, was at the root of Sir JAMES SIMPSON'S denunciations of "hospitalism" in the early "sixties" of the last century, when he had correctly observed the occurrence of septic conditions in crowded wards, but had not observed that they might occur even in isolated patients, and that the ward, although favourable to their production, was not the true cause to which they were eventually traced by LISTER, and, indeed, did not fulfil the scholastic description of a cause, "præsens facit, mutata mutat, sublata tollit." The optimist, even when he is a man of genius, requires to be especially upon his guard against the intellectual sin of hasty generalisation, and against the practical errors which indulgence in it is almost certain to entail.

The National Insurance Act.

IN the first number of the New Year it is right that we should look ahead and endeavour to forecast the future prospects of the medical profession in its relations to the public under the National Insurance Act. This duty is an extremely responsible one, because in gauging the future we must lean to one side or the other in very arguable circumstances, and the weight of deliberate opinion, based upon or reinforced by such wide communication as we have been able to maintain with the members of the medical constituency, and expressed in circumstances when so many conflicting views have their honest and keen supporters, may seriously influence the course of events. The National Insurance Act is now law, and the three questions which go to the core of the matter are the following: What is the best that can possibly befall the medical profession under it? What is the worst that can happen? And what can be done to favour the former and prevent the latter?

The best is that under the Act the medical profession should be placed in a proper position to administer faithfully and for the public weal the benefits promised to that public. Now the Act as it stands does not secure adequate or willing medical service for insured persons; there are loopholes everywhere for the extension of abuses under which the profession has long suffered, and for injustices which have sorely tried many of our readers. As Sir JOHN TWEEDY has pointed out in our columns, it abrogates the tacit agreement of the State that those who have devoted time, money, and thought to the acquisition of professional knowledge and skill, and who have secured a legal right to practise, shall be entitled to dispose of their services as they choose. But the Insurance Commissioners have been given very wide powers, and it is claimed that they can make the Act acceptable to the medical profession. The best that can befall the profession, and therefore the public, now that the moving finger has written its message and made the Act law, is that the Commissioners should fearlessly face the situation, and so frame their regulations for medical benefits that the minimum demands of medical men are safeguarded for all time. They must be fearless, for they will have to act against the expressed views of many voters whose idea of gain for themselves appears to mean loss for medical men. If the Commissioners cannot or will not do this, then the Act stands condemned from the medical point of view. But we believe that union within our ranks in the coming months can produce an impression upon the Commissioners sufficient to ensure the adjustment of the Act to the requirements of medical men before in any locality men are asked to accept service. This is the best that the future holds in store. The worst is that an Act which is generally unacceptable to our body should none the less be accepted by individual members of the medical profession, with the result that some third-rate State medical service should be generated, which, while perpetuating and exaggerating professional evils that now exist, should afford the country no real safeguard in the intended directions. Between the best and the worst there are gradations of misfortune. But the disaster above all would be for a great and honourable profession, upon which the public depends for progress and happiness, to split up at this critical time into groups and factions. If divided counsels persist during the present year, and disunion continues, we shall look in vain to the Local Insurance Committees or to the Commissioners for satisfactory terms. The after-effects of such a defeat are too painful to contemplate.

If the best is to come to pass the profession must make ready as though for an inevitable fight, and must take its stand upon one policy. The British Medical Association is the most obvious organisation by which the profession may secure its ends. Throughout the passage of the Bill we reported and discussed the course taken by the Association, and it was apparent that we did not see eye to eye with it at every point. But in the general interest we criticised as little as possible,

our view here being exactly that of the President-elect of the Association, Sir JAMES BARR, who has since pointed out that to criticise the leaders of the Association during their work of negotiation would have been intrusive. For this reason we did not publish many ventilations of opinion received by us, which might have embarrassed the action of the Association and spread disaffection in its ranks, though we considered it right to point out, from the beginning and throughout the discussions on the measure, how great was the risk lest the profession should find itself committed to all the old abuses of contract practice. But the position became profoundly changed, when it was clear that the measure was going to pass into law without containing in a satisfactory manner the minimum safeguards to obtain which so much work and diplomacy had been employed. Thus the position of the Association became the subject of comment both within its own ranks and outside. At present there are two main policies before the profession; we shall be understood if we call them respectively the policy of the Council of the British Medical Association and the policy of Manchester. The Council would work the Act as it is and trust the Commissioners to set right any wrong. The National Medical Union would refuse to accept any appointment under it without far better safeguards than the Act offers, and a Reform Committee of the British Medical Association has now been started in London with a similar objective. It is probable that on each side there is a large body of supporters which will not fight under the flag of the other; while there are also some practitioners who will not fight at all. But we believe that the great mass of the profession wishes to stand up for its rights, being able to do so on the highest public grounds, and if they can make a fairly common cause any minority will become a negligible factor. We have always declined to associate ourselves with those critics of the policy of the Council who weaken their case by personal abuse, or who spread discord by imputing base motives to those whose opinions are at variance with their own. But we hold still, as we did after the last meeting of the Representative Body, that the Council erred in judgment. It is true that its policy was endorsed by majorities at the Representative meetings; but there is evidence that some at least of the representatives were swayed in their voting by the advice of the leaders, and it is certain that for some time past the policy of negotiation and conditional approval of the Act has been steadily losing favour with the profession, while the assurance of the Council that the Act contains no legal barriers to the fulfilment of the six-fold demand of the Association has provoked much hostile comment.

Whatever may have been the merits of the plan pursued by the Council when the Bill was before Parliament, in the present pass we place our confidence in the braver of the two policies. We feel that it reflects better the considered attitude of the profession, and believe that the Commissioners, on learning the refusal of the profession to entertain the notion of local bargaining, will realise that their duty is to save the Act by ensuring justice for medicine from the outset. The policy of the Council encourages the notion in the public mind that the profession is at bottom satisfied with the Act and is merely bluffing from commercial motives; and by its faith in the Commissioners this policy commits the profession so deeply that subsequent refusal of service on an effective scale may be impossible. Neither of the reforming organisations is a clique bent upon the disruption of the British Medical Association; each numbers many among it who would take the view that the Act could be worked by the medical profession, provided that the regulations framed by the Commissioners included from the beginning explicit guarantees against the degradation of our standards of practice, against any confirmation of the worst abuses of the club system, and against conditions of livelihood which will curtail the supply of recruits to our ranks and worsen the material from which these are drawn. We recognise that the official policy of the Association has still many adherents who are not likely to approve the forcible proposals of the National Medical Union. For the sake of that united action which is now so urgently needed the official view had better be modified, for it stands in the way of union. The National Medical Union has for its object the strengthening of the hands of the British Medical Association, and if what we have termed their policy succeeds we might arrive at the position that through the executive organisation of the British Medical Association the Government and the Commissioners could learn that the medical profession will take no further part in accepting service under the Act until it has seen the regulations proposed for the administration of medical benefits. For, as Sir ALFRED PEARCE GOULD points out in our columns this week, until the regulations have been drafted and approved, the Act lacks all definition. He desires that such definition should be formulated by the medical profession, and if the great professional corporations would lend the assistance suggested in his letter, a circumstance already realised in Scotland, the course would be welcomed. But the Act is law, and we lean, in the urgency of the circumstances, to his second proposal, which is the same as that we have already put forward—viz., that the regulations should be produced for the consideration of those who have to provide the medical benefits. This is not a wholly *non possumus* attitude, and we commend it to the serious attention of our readers.

Annotations.

"Ne quid nimis."

THE NEW YEAR HONOURS.

ONLY a few weeks have passed since the issue of the Durbar honours, and it was generally expected that the New Year's list would not be a long one. Now that the list has been issued it is seen that it is indeed much shorter than the lists which usually appear at this time of the year. The medical profession has, however, been kindly treated, as six new knights have been created in our calling and one Companion of the Bath has been added to the list. The new knights are: Mr. John Hawtrey Benson, M.D. Dub., F.R.C.P. Irel., L.R.C.S. Irel.; Mr. Robert John Collie, M.D., C.M. Aberd.; Mr. James Mackenzie Davidson,

M.B., C.M. Aberd.; Mr. George Henry Savage, M.D. Lond., F.R.C.P. Lond., M.R.C.S. Eng.; Mr. Bertram Coghill Alan Windle, M.D., B.Ch. Dub.; and the Hon. Charles Kinnaird Mackellar, M.B., M.S. Glasg. Mr. Arthur Newsholme, M.D. Lond., F.R.C.P. Lond., is the new Companion of the Bath. Sir John Hawtrey Benson is the President of the Royal College of Physicians of Ireland and consulting physician to the City of Dublin Hospital and to Monkstown Hospital. Sir Robert John Collie is medical examiner to the London County Council, chief medical officer to the Metropolitan Water Board, and examiner to a large number of insurance offices. He is a well-known authority on the subject in which he has specialised and has made a particular study of injuries in relation to accident. Among his writings on accidents and their medico-legal aspect is "Observations on 17,000 Consecutive Medical Examinations Conducted Chiefly for the Public Service." Sir James Mackenzie Davidson is consulting surgeon to the Roentgen Ray Department of Charing Cross Hospital and of the same department in the Royal London Ophthalmic Hospital. He has done some important work with regard to Roentgen ray investigation and particularly in the direction of localisation. Sir George Henry Savage is consulting physician to Guy's Hospital and to Earlswood Asylum for Idiots, and is a well-known authority on mental diseases. He was formerly physician and superintendent at the Bethlem Royal Hospital, President of the Medico-Psychological Association of Great Britain and of the Neurological Society, and is the late editor of the *Journal of Mental Science*. Sir Bertram C. A. Windle is a late member of the General Medical Council for the University of Birmingham, and is now President of University College, Cork. He is a Fellow of the Royal Society and of the Society of Antiquaries and a member of the Royal Irish Academy. He is Pro-Vice-Chancellor of the National University of Ireland, Chairman of the Standing Committee of Irish Technical Education, and a Commissioner for Intermediate Education in Ireland. The Hon. Sir Charles Kinnaird Mackellar is a Member of the Legislative Council of New South Wales and President of the State Children's Relief Board. Dr. Arthur Newsholme, who has been made a Companion of the Order of the Bath, is the medical officer to the Local Government Board, examiner in public health to the University of Cambridge, Crown nominee on the General Medical Council, and Ex-President of the Society of Medical Officers of Health and of the Epidemiological Section of the Royal Society of Medicine. He is a member of the Council of the Imperial Cancer Research Fund. His public work is well known to the members of the medical profession and needs no detailed mention from us. To each of these gentlemen we extend hearty congratulations in the name of the profession to which they belong. The name of Rider Haggard, so well known as a novelist, will also be recognised as that of an authority on the economic and social conditions of rural England. Sir Henry Rider Haggard has done useful public work as chairman of the Reclamation and Unemployed Labour Committee and of the Royal Commission on Coast Erosion and Afforestation. His report on the Salvation Army's colonies in the United States and at Hadleigh, England, which he issued, together with a scheme of National Land Settlement, in 1905, as British Government Commissioner, should be remembered for its valuable suggestions in support of the self-evident proposition that a healthy family on the land forms better national material than a sick family in a slum.

DECORATIVE SURGERY.

OPERATIONS may be usefully divided into two classes—into those which are required for the life, for the health, or for at least the comfort of the sufferer, and those which are performed merely to improve the personal appearance of the patient, if we may employ here a word which connotes suffering, though no physical pain be present. For suffering there often is, and it is none the less real though it does not happen to be physical. The distinction between the two classes of operations cannot always be drawn very clearly, for there are cases which lie on the border-line. An operation for strangulated hernia is undoubtedly an operation of necessity, and equally certainly an operation for the cure of a saddle-back nose is an operation undertaken merely in order to improve the personal appearance of its owner. In these two cases the distinction is obvious. But is the cure of a hare-lip to be considered an operation of necessity or an operation performed merely for the purpose of improving the patient's looks? A cleft palate may demand an operation for the purpose of improving the nutrition of an infant, but we doubt if any will be found to assert that a hare-lip of a moderate extent interferes with feeding. If the hare-lip is of the most extreme form, even though it is not associated with a cleft of the palate, it may certainly prevent a child from taking the breast well, but it will scarcely endanger the child's life. Yet what surgeon will hesitate to perform an operation for the cure of hare-lip? There can be no doubt that physical malformations which interfere in no way with the well-being of their possessor may yet cause an immense amount of mental torture to those who have them—an amount of mental pain which can hardly be imagined by those who are formed normally. A slight hare-lip, a nose with a sunken bridge, a nose with a bulbous end, the presence of a large mole on the face, even an overgrowth of hair on the face of a woman, may, harmless though they may be in themselves, be sufficient to make the lives of their owners intensely miserable, and may in only too many cases lead to a disinclination to appear in public, which in time will become absolutely morbid. It is easy but useless for the surgeon to tell such sufferers that the malformation of which they complain is of no importance, and that it is not worth while for them to have an operation performed. These statements, sound though they may be and supported with excellent arguments, are utterly without avail, for the sufferers know and feel that the deformity is still there and that it is obvious to others. They are, indeed, often too sensitive to the opinions of others, and they think that other people notice their malformation as much as they do themselves. It is easy to smile at this morbid sensitiveness, but it is important to recognise how vital a matter it is to those who are so afflicted. Even from a pecuniary point of view these deformities are not without importance. In several occupations a young woman will find a deformity of the face a very definite bar to employment, and she may be compelled to accept a lower rate of wages in consequence. It is certain that a servant with a hare-lip or an extensive growth of hair on the face will experience no little difficulty in obtaining employment, certainly most employers will be less willing to engage such a servant than one not so disfigured. The absence of a nose may not in the least interfere with the working powers of man, but he will undoubtedly find that it will militate against his power of getting work. This diminution in the earning capacity of those who have facial deformities is very real, and the knowledge of it, and the concomitant recognition of the fact that many people have an involuntary shrinking from those who are deformed, must

act prejudicially on the mind of the victim, and if there is the least mental instability it may suffice to upset the mental equilibrium; or if it should not go so far as this it may be enough to embitter the whole life of the sufferer, and to render him a much less useful member of society than he would otherwise be. Attempts to cure, to remove, or, at least, to mitigate, all facial deformities must be regarded as a very important part of the work of a surgeon, not so important indeed as the relief of an obstruction of the bowel, or the removal of a malignant growth, but surely as important as the remedying of a knock-knee or the excision of a lipoma. Decorative surgery is not only justifiable but is really essential for a large number of people if they are to pursue effectively the business of their lives, and we have only to determine what limits there are, if any, to surgical practice in this direction. The greatest care should be taken that the operations which may be included under the heading of decorative surgery should be conducted with all the precautions that modern science has shown to be necessary. The fact that these operations are not performed with life dependent upon them, and, strictly speaking, need not be performed at all, must not persuade the surgeon to relax his watchfulness. But the responsibility of assisting the public by cosmetic operations is upon the medical profession. If surgeons will not undertake the manifold operations belonging to this class the unqualified practitioner will step in and will carry out inefficiently the work neglected by the surgeon. Without training and without due knowledge of the conditions and of the risks that are run in operating and of the precautions that should be taken, unqualified operators do grievous harm. Already they venture to undertake much that is pure surgery, and the evil is growing. It is true that the surgeon is willing to operate on hare-lips and a few of the more striking deformities, but many of the malformations he will not touch. In skilled hands the risk and danger are small, and with practice the results may be very good. The work must be undertaken as a real and important part of surgery, and when carried out with care much misery will be saved and many men and women will be rendered more capable of earning a livelihood.

THE DECLINE OF PERSONAL HONESTY.

THE Penal Reform League, in its fourth annual report which has just been issued, takes up seriously the dictum of the head constable of Liverpool that there is "a general decline of personal honesty in many relations of life." That personal honesty is widely lacking, the report states, is well known, but whether it is generally declining there are no means of knowing. In any case, considering the prevalence of social and economic injustice, the unequal distribution of wealth, party strife in economics, politics, and religion, unfit parents and homes, and the stunting effect of schools, what right, it asks, have we to expect anything else? As signs of an awaking conscience in these matters, the report refers to the National Conference on the Prevention of Destitution, held last summer, the First International Congress on Children's Courts, and various other congresses touching cognate subjects. The tours of inspection of the secretary of the league, Captain Arthur J. St. John, lead him to comment on the over centralisation in this country, as compared, for instance, with the methods in vogue in America. He especially urges that children's places of detention should be under the charge of gentlewomen of exceptional attainments. He reviews the prevailing conditions in English, Scotch, and Irish prisons, and concludes that "neither the British Public nor their magistrates have yet grasped the whole meaning and possibilities of probation or of the juvenile court," which in his opinion should be not "a police court with children instead of adult offenders, but an aggressive child protecting agency." It is urged that the intelligent acceptance of Mr. Edmond Holmes's thesis, that "the function of education is to foster growth," must lead to a peaceful revolution in our ideas and our common life that in time will transform our whole criminal procedure and result in the disappearance of prisons. In two appendices are published certain suggestions for penal reform, of which the following seem to be the more important: Inebriates, mental defectives, and debtors should not be imprisoned, but treated or cared for; the replacing of imprisonment by probation or training for offenders under 23 years, the principle of probation being better organised and more widely extended; organisation of prison industries with a view to giving instruction in methods of gaining a livelihood, clothing prisoners better, and the training of character; the establishment of carefully organised parole or after-care system, and of prison farms and colonies; the holding of juvenile courts quite apart from other courts, in juvenile houses of detention and under special magistrates; and a change of *personnel* in prison administration, in respect of an improved method of selection of officials and a marked improvement in the conditions of life of prison officers.

GENERAL INFECTION WITH THE COLON BACILLUS PRODUCING DOUBLE PNEUMONIA AND PURULENT BRONCHITIS.

IN recent years it has been recognised that the colon bacillus may infect various parts of the body, producing inflammation. Infections of the urinary tract are the best recognised and may take the form of nephritis, pyelonephritis, pyelitis, or cystitis. Of lesions in other parts little is yet known. In THE LANCET of Oct. 30th, 1909, p. 1269, Dr. J. Charlton Briscoe reported several cases of matting together of the pelvic viscera by an exudate showing caseous changes and suggesting tuberculosis, but microscopic examination showed that the lesions were due to the colon bacillus, which was also found abundantly in the urine. In the *Boston Medical and Surgical Journal* of Nov. 30th, 1911, Dr. R. C. Kemp has reported a case of general infection with the colon bacillus in which double pneumonia and purulent bronchitis were produced. A man, aged 44 years, was operated on in the New York Hospital for right inguinal hernia on March 2nd, 1910. He was in perfect physical condition and his organs were found normal on examination. Though he took much exercise he was subject to constipation, for which he used olive oil and other simple remedies. On the afternoon of the day of operation catheterisation was necessary. On the next day there was some irritation of the bladder, which was washed out. On the following day there was pain in the left renal region and the urine contained pus. Pyelitis was diagnosed and urotropine was given. In three or four days the pain disappeared and then the right kidney was affected, but not so severely as the left. The pain on the right side soon disappeared, but pyuria and slight pyrexia continued. On March 11th he complained of pains in the right side of the chest, and on the 12th dry pleurisy was found. On the 14th a small pneumonic area was found at the right base. On the 16th there was an alarming attack of heart failure with a fall of temperature. Under digitalin, strychnine, hypodermic injection of camphor in olive oil, hot stupes, and inhalation of oxygen he rallied. On the 24th there was a rigor, and the temperature rose to 104° F. As there was still evidence of pyelitis this suggested infection with the colon bacillus, which was found in the urine in large numbers. Resolution of the lesion in the right lung was very slow. There was little sputum, but in it abundant colon bacilli were found

Early in May a sharp attack of colitis occurred. Subsequently, an attack of pneumonia at the left base with mild symptoms took place. The colon bacillus was again found in the sputum. In May a sudden attack of acute purulent bronchitis occurred. So thick was the pus that a pulmonary abscess was feared. On culture enormous numbers of colon bacilli and some streptococci were found. As there was still pneumonic expectoration it seemed that the bronchitis was due to infection from the pneumonia. Under autogenous vaccines the bronchitis improved, but the colon bacilli persisted in the urine. In June an exacerbation of the pyelitis occurred, and coincided with a second attack of colitis—a very suggestive fact. Ulcer of the colon was suspected, but examination of the stools for pus or occult blood was negative. In July the bacilluria with a few pus cells still persisted, and the evening temperature was 99° to 99·5° F. On August 7th the urine was found free from colon bacilli. It remained so until October, when the patient returned to business. Against advice he did a full day's work. About the fourth day he had a chill and rise of temperature, and colon bacilli reappeared in the urine, but not in great numbers. He was then sent to the South of France. In December he wrote that only a few colon bacilli could be found in the urine and that his temperature was normal. Throughout the illness urotropine and sodium benzoate were given, at one time 80 grains of each daily.

THE EVIDENCE FOR THE SUPERNATURAL.

No one goes far along a medical career (or any other, for that matter) without being asked whether he believes in telepathy, or ghosts, or clairvoyance, or some other allied manifestation of supernatural forces. Whether sceptic or believer he will meet with most circumstantial histories in support of such manifestations, yet almost never at first hand. However sceptical he be, he can hardly fail to be struck by the perpetual recurrence of supposed examples of supernatural manifestations and by the firmness of conviction which these histories engender in people apparently well balanced, and he may wonder how it is that, if there be no truth in the business, such beliefs have not long since shared the fate of witchcraft and necromancy. Those who wish to find a solution to these questions may be recommended to read a book by Dr. Ivor Tuckett,[1] the title of which we have borrowed for this annotation. In it they will find a cool and critical review of the evidence both for and against the supernatural, by one who has had no personal part or lot in procuring the evidence, who has no first-hand knowledge of séances and the like, but has simply set himself to a detached survey of the recorded evidence of experimenters in this field. Undoubtedly the witness of such a critic is entitled to more weight than that of actual participants in the proceedings analysed, especially in such a hazy matter as this, wherein sober judgment is continually threatened by subjective traps and pitfalls. It is sometimes rashly assumed that a scientific training is a sufficient qualification for the investigation of these subtle subjects, and that if a scientist of high standing in his own line announces his belief in spiritualism, let us say, the case for spiritualism at once receives a backing proportionate to the scientist's pre-eminence in physics or what not. This is not the least important of the many fallacies which envelope this elusive subject; for the adhesion to supernatural beliefs of men so eminent as Sir Oliver Lodge and Sir William Crookes has undoubtedly influenced many waverers. Yet it is obvious that those who by training are well accustomed to be critical with regard to experiments conducted under laboratory conditions, conditions whose first element is constancy of the items forming the experiment, may be poor critics of experiments whose circumstances are always vague and never twice identical. It is true to say that a practical knowledge of conjuring in all its branches, combined with training in psychology, is a better endowment for the investigator in these paths than any other scientific equipment, be the latter never so ample. Those who read this book will find in it a temperate and balanced estimate of the evidence for supernatural interference in the daily affairs of men. It is not everyone who will relish its conclusions all along the line, but it is decidedly a book to be read by all who are interested in human psychology; and every practitioner of medicine ought to place himself in this category.

[1] The Evidence for the Supernatural. By Ivor Ll. Tuckett, M.D. London: Kegan Paul. 1911. Pp. 399. Price 7s. 6d. net.

THE OPHTHALMOSCOPE IN GENERAL PRACTICE.

IT is a commonplace of the text-books that the ophthalmoscope can often bring light upon the diagnosis of extra-ocular diseases, and its use for this purpose was greatly increased by the pioneer work of Hughlings Jackson and Gowers in this country. At the same time it is open to doubt whether this instrument is so generally employed as a routine agent in the diagnosis of obscure cases in the general practice of medicine as its value and importance would indicate. From the character of the information it affords, it is worthy to rank with the stethoscope and the thermometer, and indeed it may afford in many instances information which is either pathognomonic or highly suggestive in regard to diagnosis. It is, moreover, in comatose cases and those from whom no history is obtainable that the ophthalmoscope may be of special value. In illustration we may mention some of the conditions which it is easy to recognise with a very little practice and experience in the use of the ophthalmoscope. The appearance of optic neuritis and papillitis in cerebral or cerebellar tumours is well known as one of the most significant signs of these conditions, but it may be doubted whether the ophthalmoscope is generally employed as it should be in all cases of persistent headache, in all forms of convulsions or fits, and in cases with marked neurotic or hysterical manifestations. The mistaking of a brain tumour for hysteria is by no means an infrequent occurrence, and the diagnosis is often only determined by ophthalmoscopic examination. The various forms of neuro-retinitis may also be of importance in diagnosis and lead to the discovery of chronic nephritis and diabetes. It is said that albuminuric neuro-retinitis occurs in from 15 to 20 per cent. of all cases of chronic nephritis, especially of the interstitial variety. The discovery of syphilitic choroiditis on examination of the fundus may serve in an obscure case of visceral disease or of nervous lesion to indicate its nature and suggest a more hopeful prognosis and a specific line of treatment. The recognition of optic atrophy may be an important link in the diagnosis of some chronic diseases of the central nervous system, such as locomotor ataxy, disseminated sclerosis, and general paralysis of the insane, or may serve to suggest the occurrence of lead poisoning as an explanation of obscure nervous symptoms. The vascular conditions of the retina may also be of great importance, and the finding of retinal hæmorrhages may throw light upon the nature of some chronic anæmias, or suggest the presence of chronic nephritis. Embolism of the central artery in a difficult case of chronic fever may reveal the malignant character of the endocarditis causing it. Other examples may be mentioned in the pulsation of the retinal arteries in aortic disease and the so-called "silver-wire" arteries of chronic interstitial nephritis. The occurrence of tubercles in the choroid in general miliary tuberculosis may also be of great importance

XVIIth International Congress of Medicine.

LONDON 6th–12th AUGUST, 1913.

January, 1912.

DEAR SIR,—We beg to inform you that the XVIIth International Medical Congress will be held in London from August 6th to August 12th, 1913, inclusive.

His Majesty King George V. has graciously accorded his patronage to the Congress.

In the name of the Organising Committee of the Congress we beg leave to invite you to take an active part therein. The Rules, which you will find annexed, will give you all the necessary preliminary information.

The programme of the Congress and of its various Sections, including the arrangements for general meetings and for the general discussions in the Sections, will be published not later than September 30th, 1912, and will be forwarded to all those who shall at that time have inscribed themselves as members of the Congress.

We beg to append a form of application for membership and should be glad if you would inscribe your name as a member of Congress at the earliest possible opportunity.

An appeal will shortly be made to the profession for funds to meet the necessary expenses of the organisation of the Congress, which, it is estimated, will be not less than £8000, exclusive of the subscriptions of members.

We have the honour to remain, dear Sir, yours obediently,

THOMAS BARLOW, President.
W. P. HERRINGHAM, General Secretary.

OFFICERS OF CONGRESS.

President.—Sir THOMAS BARLOW, Bt., K.C.V.O., LL.D., M.D., President R.C.P., F.R.S.

Vice-Presidents.—Sir W. S. CHURCH, Bt., K.C.B., LL.D., D.C.L., M.D., F.R.C.P.; Sir JONATHAN HUTCHINSON, LL.D., F.R.C.S., F.R.S.; Rt. Hon. Lord LISTER, O.M., LL.D., D.C.L., M.D., F.R.C.S., F.R.S.; Professor JAMES LITTLE, LL.D., M.D., F.R.C.P.I; Sir R. DOUGLAS POWELL, Bt., K.C.V.O., LL.D., M.D., F.R.C.P.; Sir FREDERICK TREVES, Bt., G.C.V.O., C.B., LL.D., M.D., M.Ch., F.R.C.S.; Sir WM. TURNER, K.C.B., LL.D., D.C.L., F.R.C.S. Ed., F.R.C.S., F.R.S., F.R.S. Ed.; Sir HERMANN WEBER, M.D., F.R.C.P.

Treasurers.—Sir DYCE DUCKWORTH, Bt., LL.D., M.D., F.R.C.P.; G. H. MAKINS, C.B., F.R.C.S.

Chairman of Executive Committee.—Sir ALFRED PEARCE GOULD, K.C.V.O., M.S., F.R.C.S.

Honorary General Secretary.—W. P. HERRINGHAM, M.D., F.R.C.P.

Section I.—Anatomy and Embryology.

President.—Professor Arthur Thomson, M.B., F.R.C.S.

Vice-Presidents.—C. B. Lockwood, F.R.C.S.; Professor Alexander Macalister, LL.D., M.D., F.R.S.; Professor R. W. Reid, M.D., F.R.C.S.; Professor J. Symington, M.D., F.R.C.S. Ed., F.R.S.; Professor G. D. Thane, LL.D., F.R.C.S.

Secretaries.—Professor R. Howden, M.B., C.M., F.R.S. Ed.; Alexander Macphail, M.B., C.M., F.F.P.S.

Section II.—Physiology.

President.—Professor E. A. Schäfer, LL.D., M.D., F.R.S.

Vice-Presidents.—Professor Francis Gotch, D.Sc., M.R.C.S., F.R.S.; Leonard E. Hill, M.B., F.R.S.; Professor J. G. McKendrick, LL.D., M.D., C.M., F.R.C.P. Ed., F.R.S., F.R.S. Ed.; Professor C. S. Sherrington, LL.D., M.D., F.R.S.; Professor E. H. Starling, M.D., F.R.C.P., F.R.S.; Professor Wm. Stirling, M.D., F.R.S. Ed.; A. D. Waller, M.D., F.R.S.

Secretaries.—J. S. Edkins, D.Sc., M.B.; Professor W. D. Halliburton, LL.D., M.D., F.R.C.P., F.R.S.; Professor D. Noel Paton, M.D., F.R.C.P. Ed., F.R.S. Ed.; Professor W. H. Thompson, M.D., M.Ch., F.R.C.S.

Section III.—General Pathology and Pathological Anatomy.

President.—S. G. Shattock, F.R.C.S.

Vice-Presidents.—F. W. Andrewes, M.D., F.R.C.P.; Professor W. S. Greenfield, M.D., F.R.C.P. Ed., F.R.C.S. Ed.; A. C. O'Sullivan, M.B., B.Ch., B.A.O.; Professor J. Lorrain Smith, M.D., F.R.S.

Secretaries.—Charles Bolton, M.D., F.R.C.P.; Leonard S. Dudgeon, F.R.C.P.; James Ritchie, M.D., F.R.C.P. Ed.

Subsection.—Chemical Pathology.

President.—F. Gowland Hopkins, D.Sc., M.B., F.R.S.

Vice-Presidents.—Professor I. Walker Hall, M.D.; Professor Benjamin Moore, D.Sc., M.R.C.S., L.R.C.P.

Secretaries.—J. F. Gaskell, M.B., B.C., M.R.C.P.; J. G. Priestley, M.B., B.Ch.; J. H. Ryffel, B.C.

Section IV.—Bacteriology and Immunity.

President.—Professor G. Sims Woodhead, LL.D., M.D., F.R.C.P. Ed., F.R.S. Ed.

Vice-Presidents.—Professor G. Dreyer, M.D.; C. J. Martin, D.Sc., M.B., F.R.S.; Professor R. Muir, M.D., F.R.C.P. Ed., F.F.P.S.; Sir Almroth E. Wright, M.D., F.R.C.S.I., F.R.S.

Secretaries.—A. E. Boycott, M.D.; Carl H. Browning, M.D.; Professor E. J. McWeeney, M.D., F.R.C.P.I.

Section V.—Therapeutics (Pharmacology, Physiotherapy, Balneology).

President.—Sir Lauder Brunton, Bt., LL.D., M.D., F.R.C.P., F.R.S.

Vice-Presidents.—Professor John Buckley Bradbury, M.D., F.R.C.P., F.R.S.Ed.; Professor J. Theodore Cash, M.D., F.R.S.; Professor A. R. Cushny, M.D., F.R.S.; Professor Sir Thomas R. Fraser, LL.D., M.D., F.R.C.P. Ed., F.R.S., F.R.S. Ed.; Sir John Moore, M.D., D.Sc., D.P.H., F.R.C.P.I.; Sir James Sawyer, M.D., F.R.C.P., F.R.S. Ed.; Professor Walter G. Smith, M.D., F.R.C.P.I.; Professor R. Stockman, M.D., F.R.C.P. Ed., F.F.P.S., F.R.S. Ed.; Professor Nestor Tirard, M.D., F.R.C.P.; Professor Sir Wm. Whitla, LL.D., M.D.

Secretaries.—Professor W. E. Dixon, M.D.; R. A. Young, M.D., F.R.C.P.

Section VI.—Medicine.

President.—Professor Sir Wm. Osler, Bt., M.D., F.R.C.P., F.R.S.

Vice-Presidents.—Sir James O. Affleck, LL.D., M.D., F.R.C.P. Ed., F.R.C.S. Ed.; Sir Clifford Allbutt, K.C.B., LL.D., M.D., F.R.C.P., F.R.S.; Sir Wm. Allchin, M.D., F.R.C.P., F.R.S. Ed.; Professor Samson Gemmell, M.D., F.F.P.S.; Professor J. A. Lindsay, M.D., M.Ch., F.R.C.P., Sir Christopher J. Nixon, Bt., LL.D., M.D., F.R.C.P.I.; Professor Sir G. H. Philipson, LL.D., D.C.L., M.D., F.R.C.P.; Frederick Taylor, M.D., F.R.C.P.

Secretaries.—John Cowan, M.D., F.F.P.S.; A. E. Garrod, M.D., F.R.C.P., F.R.S.; G. Lovell Gulland, M.D., F.R.C.P. Ed.; A. R. Parsons, M.D., F.R.C.P.I.; W. Pasteur, M.D., F.R.C.P.; H. D. Rolleston, M.D., F.R.C.P.; W. Hale White, M.D., F.R.C.P.

Section VII.—Surgery.

President.—Professor Sir Wm. Watson Cheyne, Bt., C.B., LL.D., M.B., C.M., F.R.C.S., F.R.S.

Vice-Presidents.—Sir Chas. B. Ball, Bt., M.D., F.R.C.S.I., F.R.C.S.; Sir William H. Bennett, K.C.V.O., F.R.C.S.; Sir H. T. Butlin, Bt., D.C.L., LL.D., F.R.C.S.; John Chiene, C.B., LL.D., M.D., F.R.C.S. Ed., F.R.S. Ed.; Professor R. J. Godlee, M.S., President R.C.S.; Sir Alfred Pearce Gould, K.C.V.O., M.S., F.R.C.S.; Professor Sir Wm. Macewen, LL.D., M.D., F.F.P.S., F.R.C.S., F.R.S.; Professor Howard Marsh, M.C., F.R.C.S.; Sir Henry Morris, Bt., F.R.C.S.

Secretaries.—Raymond Johnson, B.S., F.R.C.S.; D'Arcy Power, F.R.C.S.; Professor T. Sinclair, M.D., M.Ch., F.R.C.S.; Professor Wm. Thorburn, M.D., B.S., F.R.C.S.

Subsection A.—Orthopædics.

President.—Robert Jones, Ch.M., F.R.C.S. Ed.

Vice-President.—Ernest Muirhead Little, F.R.C.S.

Secretaries.—R. C. Elmslie, M.S., F.R.C.S.; T. H. Openshaw, C.M.G., M.S., F.R.C.S.

Subsection B.—Anæsthesia, General and Local.

President.—Dudley W. Buxton, M.D., B.S., M.R.C.P.

Vice-Presidents.—George M. Foy, M.D., F.R.C.S.I.; D. C. A. McAllum, M.B., C.M.; J. F. W. Silk, M.D.

Secretaries.—H. J. Scharlieb, C.M.G., M.D., F.R.C.S.; J. W. Struthers, M.B., Ch.B., F.R.C.S. Ed.

Section VIII.—Obstetrics and Gynæcology.

President.—Sir Francis H. Champneys, Bt., M.D., F.R.C.P.

Vice-Presidents.—Professor Sir J. W. Byers, M.D., M.Ch., M.A.O.; Professor Murdoch Cameron, M.D.; Professor Sir J. Halliday Croom, M.D., F.R.C.P. Ed., F.R.C.S. Ed., F.R.S. Ed.; Alban Doran, F.R.C.S.; G. E. Herman, M.B., F.R.C.P., F.R.C.S.; H. Macnaughton Jones, M.D., M.Ch., M.A.O., F.R.C.S.I., F.R.C.S. Ed.; Professor E. Malins, M.D., F.R.C.P.; David Lloyd Roberts, M.D., F.R.C.P.; Professor Sir Wm. Sinclair, M.D.; Sir W. J. Smyly, M.D., F.R.C.P.I., F.R.C.S.I.; Professor W. Stephenson, M.D., F.R.C.S. Ed.

Secretary.—Herbert Spencer, M.D., F.R.C.P.

Section IX.—Ophthalmology.

President.—Sir Henry Swanzy, M.D., F.R.C.S.I.
Vice-Presidents.—George A. Berry, M.B., C.M., F.R.C.S. Ed., F.R.S. Ed.; W. A. Brailey, M.D.; Sir Anderson Critchett, Bt., C.V.O., F.R.C.S. Ed.; F. R. Cross, F.R.C.S.; Edward Nettleship, F.R.C.S.; Charles Higgens, F.R.C.S.; Priestley Smith, F.R.C.S.
Secretaries.—E. Treacher Collins, F.R.C.S.; J. B. Lawford, M.D., C.M., F.R.C.S.; George Mackay, M.D., F.R.C.S. Ed.; Louis Werner, F.R.C.S.I.

Section X.—Diseases of Children.

President.—Eustace Smith, M.D., F.R.C.P.
Vice-Presidents.—Sir J. F. Goodhart, Bt., LL.D., M.D., F.R.C.P.; D. B. Lees, M.D., F.R.C.P.; Edmund Owen, LL.D., F.R.C.S.; H. J. Stiles, F.R.C.S. Ed.; John Thomson, M.D., F.R.C.P. Ed.; Professor George A. Wright, F.R.C.S.
Secretaries.—J. G. Emanuel, M.D.; A. M. Gossage, M.D., F.R.C.P.; T. H. Kellock, M.D., M.C., F.R.C.S.; Professor G. F. Still, M.D., F.R.C.P.

Section XI.—Neuropathology.

President.—Sir David Ferrier, LL.D., M.D., F.R.C.P., F.R.S.
Vice-Presidents.—Byrom Bramwell, M.D., F.R.C.P. Edin., F.R.S. Edin.; T. Buzzard, M.D., F.R.C.P.; Sir W. R. Gowers, LL.D., M.D., F.R.C.P., F.R.S.
Secretaries.—Fred E. Batten, M.D., F.R.C.P.; H. Head, M.D., F.R.C.P., F.R.S.

Section XII.—Psychiatry.

President.—Sir James Crichton-Browne, LL.D., M.D., F.R.S., F.R.S. Ed.
Vice-Presidents.—Sir T. S. Clouston, LL.D., M.D., F.R.C.P. Edin.; Sir G. H. Savage, M.D., F.R.C.P.
Secretaries.—C. Hubert Bond, M.D.; Maurice Craig, M.D., F.R.C.P.; Edwin Goodall, M.D., F.R.C.P.; James H. MacDonald, M.B., Ch.B.

Section XIII.—Dermatology and Syphilography.

President.—Sir Malcolm Morris, K.C.V.O., F.R.C.S. Ed.
Vice-Presidents.—Wallace Beatty, M.D., F.R.C.P.I.; Henry Fitzgibbon, M.D., F.R.C.S.I.; T. Colcott Fox, M.B., F.R.C.P.; James Galloway, M.D., F.R.C.P.; W. Allan Jamieson, M.D., F.R.C.P. Ed.; J. Ernest Lane, F.R.C.S.; Alexander Morton, M.D.; J. J. Pringle, M.B., C.M., F.R.C.P.; J. H. Stowers, M.D.; Norman Walker, M.D., F.R.C.P. Ed.
Secretaries.—R. Cranston Low, M.B., Ch.B., F.R.C.P. Ed.; J. M. H. MacLeod, M.D.; H. Leslie Roberts, M.D.; J. H. Sequeira, M.D., F.R.C.P., F.R.C.S.

Section XIV.—Urology.

President.—Professor E. Hurry Fenwick, F.R.C.S.
Vice-Presidents.—F. Swinford Edwards, F.R.C.S.; David Newman, M.D., F.F.P.S.; F. A. Southam, F.R.C.S.
Secretaries.—Cyril A. R. Nitch, M.S., F.R.C.S.; John G. Pardoe, F.R.C.S.

Section XV.—Rhinology and Laryngology.

President.—Professor StClair Thomson, M.D., F.R.C.P., F.R.C.S.
Secretaries.—W. D. Harmer, M.C., F.R.C.S.; A. Brown Kelly, M.D.; Dan McKenzie, M.D., F.R.C.S. Ed.

Section XVI.—Otology.

President.—Arthur Cheatle, F.R.C.S.
Vice-Presidents.—Thomas Barr, M.D., F.F.P.S.; T. Mark Hovell, F.R.C.S. Ed.; Edward Law, M.D.; Wm. Milligan, M.D.; Professor Urban Pritchard, M.D., F.R.C.S.
Secretaries.—J. S. Fraser, F.R.C.S. Ed.; G. J. Jenkins, M.B., C.M., F.R.C.S.; Sydney Scott, M.S., F.R.C.S.; Professor John B. Story, M.Ch., F.R.C.S.I.

Section XVII.—Stomatology.

President.—Morton A. Smale, M.R.C.S., L.D.S.
Vice-Presidents.—A. W. W. Baker, M.D., F.R.C.S.I., L.D.S.; F. J. Bennett, M.R.C.S., L.D.S.; E. A. Bevers, M.R.C.S.; J. H. Gibbs, F.R.C.S. Edin., L.D.S.; Frank Harrison, M.R.C.S., L.D.S.; W. A. Hooton, M.R.C.S., L.R.C.P., L.D.S.; Edwd. Lloyd-Williams, M.R.C.S., L.R.C.P., L.D.S.; W. A. Maggs, M.R.C.S., L.R.C.P., L.D.S.; Sidney Spokes, M.R.C.S., L.D.S.; Charles S. Tomes, F.R.C.S., LL.D., F.R.S.; Professor Arthur Underwood, M.R.C.S., L.D.S.
Secretary.—J. F. Colyer, M.R.C.S., L.R.C.P., L.D.S.

Section XVIII.—Hygiene and Preventive Medicine.

President.—Arthur Newsholme, M.D., F.R.C.P.
Vice-Presidents.—Professor Sir Charles Cameron, C.B., M.D., F.R.C.P.I., F.R.C.S.I.; Professor Sheridan Delépine, M.B., C.M., M.Sc.; Professor Edward W. Hope, M.D.; W. Leslie Mackenzie, M.D., F.R.C.P. Ed., F.R.S. Ed.; Sir Shirley F. Murphy, F.R.C.S., Sir George Newman, M.D., F.R.S. Ed.; Edward C. Seaton, M.D., F.R.C.P.; T. J. Stafford, C.B., F.R.C.S. I.; Sir Arthur Whitelegge, K.C.B., M.D., F.R.C.P.
Secretaries.—A. S. Arkle, M.R.C.S., L.R.C.P.; J. C. G. Ledingham, D.Sc., M.B., Ch.B.; G. F. McCleary, M.D.; W. G. Willoughby, M.D.

Section XIX.—Forensic Medicine.

President.—Professor Harvey Littlejohn, M.B., C.M., F.R.C.S. Ed., F.R.S. Ed.
Vice-Presidents.—Professor John Glaister, M.D., F.F.P.S., F.R.S. Ed.; Professor Matthew Hay, LL.D., M.D., F.R.C.P. I.; Professor R. J. Kinkead, M.D.; Professor John Dixon Mann, M.D., F.R.C.P.; David Nicolson, C.B., M.D.
Secretary.—W. A. Brend, M.B.

Section XX.—Naval and Military Medicine.

President.—Surgeon-General Sir James Porter, K.C.B., M.A., M.D., K.H.P., Director-General Medical Department, R.N.
Vice-Presidents.—Surgeon-General Sir Launcelotte Gubbins, K.C.B., M.V.O., M.B., M.Ch., K.H.S., Director-General, A.M.S.; Surgeon-General Sir Charles P. Lukis, K.C.S.I., M.D., F.R.C.S., Director-General, I.M.S.
Secretaries.—Naval: Fleet-Surgeon G. T. Collingwood, M.V.O., M.R.C.S., L.R.C.P., R.N.; Military: Major C. E. Pollock, M.R.C.S., L.R.C.P., R.A.M.C.; Indian Medical Service: Captain A. P. G. Lorimer, M.B., I.M.S.

Section XXI.—Tropical Medicine.

President.—Colonel Sir David Bruce, C.B., LL.D., M.B., C.M., F.R.C.P., F.R.S.
Vice-Presidents.—Lt.-Col. Sir W. B. Leishman, M.B., C.M., R.A.M.C., F.R.S.; Professor Sir Ronald Ross, K.C.B., LL.D, F.R.C.S., F.R.S.; F. M. Sandwith, M.D., F.R.C.P.
Secretary.—Arthur G. Bagshawe, M.B., B.C.

Section XXII.—Radiology.

President—Sir J. Mackenzie Davidson, M.B., C.M.
Vice-Presidents.—W. Deane Butcher, M.R.C.S.; C. Thurston Holland, M.R.C.S., L.R.C.P.; H. Lewis Jones, M.D., F.R.C.P.; Hugh Walsham, M.D., F.R.C.P.
Secretary.—G. Harrison Orton, M.D.

RULES OF CONGRESS.

ART. 1.—The Seventeenth International Congress of Medicine will be held under the august patronage of His Most Gracious Majesty George V., King and Emperor.

ART. 2.—The Congress will be opened on 6th August, and will close on 12th August, 1913.

At the time of Congress the Central Bureau will be located in the Royal Albert Hall, Kensington Gore, W., and will be opened for the inscription of Members on Tuesday, 5th August, at 10 a.m.

ART. 3.—The object of the Congress is exclusively scientific.

ART. 4.—The Members of the Congress will be: (*a*) Qualified members of the medical profession, who have made formal application, and have paid the subscription hereinafter fixed; (*b*) scientific men who have been nominated by a National Committee or by the Executive Committee, and have paid the same subscription.

ART. 5.—The subscription is: £1 sterling; 25 kroner (Austria); 25 francs; 20 marks; 15 rupees; 20 kroner (Norway); 5 dollars (United States or Canada).

The wives and daughters of Members of Congress desiring to profit by the advantages accorded to them must pay half the subscription fee.

Subscriptions should be sent by postal order or cheque payable to the Treasurers, XVIIth International Congress of Medicine, and the Section in which each member wishes to be inscribed must be indicated. In the case of any country in which there is no system of international postage exchange the services of a banker must be employed. No one can be enrolled as member of Congress before the receipt of his subscription.

An applicant when sending his subscription should enclose his visiting card indicating his medical qualifications and titles and his full postal address. Any change of address must be immediately notified. Cards of Membership will be sent out from the Central Office of the Congress within eight days following the receipt of the subscription.

ART. 6.—Members of Congress will receive the volume of the Transactions recording the proceedings at the general Sessions, as well as the Transactions of the Section in which they have been inscribed.

ART. 7.—The Sections of the Congress are 22 in number, besides which three subsections are established, namely:—I. Anatomy and Embryology; II. Physiology; III. General Pathology and Pathological Anatomy; III*a*. (Subsection) Chemical Pathology; IV. Bacteriology and Immunity; V. Therapeutics (Pharmacology, Physiotherapy, Balneology); VI. Medicine; VII. Surgery; VII*a*. (Subsection) Orthopædics; VII*b*. (Subsection) Anæsthetics; VIII. Obstetrics and Gynæcology; IX. Ophthalmology; X. Diseases of Children; XI. Neuropathology; XII. Psychiatry; XIII. Dermatology and Syphilography; XIV. Urology; XV. Rhinology and Laryngology; XVI. Otology; XVII. Stomatology; XVIII. Hygiene and Preventive Medicine; XIX. Forensic Medicine; XX. Naval and Military Medicine; XXI. Tropical Medicine; XXII. Radiology.

ART 8.—The organisation of the Congress is in the hands of the Organising and Executive Committees.

ART. 9.—There will be two General Meetings of the Congress, the Inaugural Meeting and the Closing Meeting.

At these meetings the speakers will be the Government Delegates who have been invited by the Organising Committee or designated as such, and these alone. At the Closing Meeting the President will announce the city in which the next Congress will be held. This will be determined by the Permanent Commission which will sit during the Congress.

ART. 10.—The scientific work of the Congress will consist in:—(*a*) general sessions; (*b*) sectional sessions; (*c*) combined sessions of two or more Sections.

ART. 11.—The number of general sessions and the number of speakers will be fixed by the Executive Committee. There will be no debates in the general sessions.

ART. 12.—The sessions of the Sections will be occupied in formal discussions on the Reports (*rapports*), also by the reading and discussion of papers on subjects chosen by individual members of Congress. The work ot the Sections is dealt with in separate regulations.

ART. 13.—Two or more Sections may hold combined sessions.

ART. 14.—Members of Congress may take part in the proceedings of Sections other than that in which they have been inscribed.

ART. 15.—The speeches delivered at the Opening and Closing General Meetings, as well as the Reports opening formal discussions, will be published in full. As to communications on subjects selected by individual members, only those papers will be published which the authors have personally presented to the Congress, and the Executive Committee, after consultation with the Sectional Committees, has decided to publish.

ART. 16.—The manuscripts of speeches delivered at the General Meetings must be sent to the General Secretary. The manuscripts of remarks made in discussions and papers read by individual members at the Sectional Sessions must be delivered immediately (*see* Art. 14 of the Sectional Rules) to the Secretary of the Section concerned.

ART. 17.—The Central Office of the Congress will use the English, French, and German languages for international business. In the General Meetings Italian may be used as well as these languages.

ART. 18.—All correspondence should be addressed to the offices of the Congress, as follows:—

The Hon. Gen. Secretary,
XVIIth International Congress of Medicine,
13, Hinde-street, London, W.

On the envelopes of letters relative to the scientific work of the Sections, the Section to which they refer should be specified.

ART. 19.—Information concerning the reductions in fares granted by railway companies, hotel and boarding accommodation, excursions, &c., will be published before the 30th April, 1913.

RULES OF SECTIONS.

ART. 1.—The Sections will meet at 9.30 a.m. and at 3 p.m.

ART. 2.—The first Session of each Section will be opened on Wednesday, 6th August, at 3 p.m.

ART. 3.—The President of the Section will be responsible for the conduct of the discussions, for the application of the rules, and for the punctual accomplishment of the work of the Secretaries. If the President is prevented from being present at any Session of his Section, his place will be taken by one of the Vice-Presidents or by a Member of the Council of the Section.

ART. 4.—There will be no Honorary Presidents of Sections.

ART. 5.—The Sessions will be conducted according to the Parliamentary regulations in general usage.

ART. 6.—The Sessions will include discussions on the Reports and the reading and discussion of papers on subjects selected by individual Members.

ART. 7.—Reports (*rapports*). In each Section the morning Session will be reserved for the discussion of important questions which have been previously selected by the Council of the Section. Each discussion will be introduced by one or two Reporters chosen by the Council of the Section with due regard to the International character of the Congress. The definite programme of the discussions will be published on September 30th, 1912. The manuscripts of the Reports must be typewritten, and must be sent to the Central Office

Cut here.

XVIIth INTERNATIONAL CONGRESS OF MEDICINE.

LONDON, AUGUST 6th-12th, 1913.

No. _____

SECTIONS:

i. Anatomy and Embryology.
ii. Physiology.
iii. General Pathology and Pathological Anatomy.
(Sub-Section) Chemical Pathology.
iv. Bacteriology and Immunity.
v. Therapeutics.
vi. Medicine.
vii. Surgery.
(Sub-Section) Orthopædics.
(Sub-Section) Anæsthesia.
viii. Obstetrics and Gynæcology.
ix. Ophthalmology.
x. Diseases of Children.
xi. Neuropathology.
xii. Psychiatry.
xiii. Dermatology and Syphilography.
xiv. Urology.
xv. Rhinology and Laryngology.
xvi. Otology.
xvii. Stomatology.
xviii. Hygiene and Preventive Medicine.
xix. Forensic Medicine.
xx. Naval and Military Medicine.
xxi. Tropical Medicine.
xxii. Radiology.

To the HON. GENERAL SECRETARY.

Dear Sir,

I beg to ask you to inscribe my name as a member of Congress in the _____ *th Section, and to forward my subscription of* _____ *by Postal Money Order.*

Date _____

Name in full _____

Medical Qualifications _____

_____

Other Titles _____

Full Address _____

Kindly attach your visiting card, and please write distinctly.

I beg also to forward subscriptions for:—

1. MY WIFE—*Name in full* _____

Address _____

2. MY DAUGHTER—*Name in full* _____

Address _____

This application should be returned to The General Secretary, XVIIth International Congress of Medicine, 13, Hinde-street, London, W. Subscriptions (see Rules of Congress, Art. 5) are payable to the Treasurers, and must be enclosed with the application.

of the Congress by February 28th, 1913, at the latest. The Reports of each Section will be printed and distributed three months before the opening of the Congress, to all members of the Section who have then been enrolled. (See Rules of Congress, Articles 4 and 5.) The reports will not be read *in extenso* at the session. Each reporter will, however, be allowed a maximum of 15 minutes for an opening *résumé*, and 10 minutes for a reply at the end of the discussion Other speakers taking part in the discussion will be allowed a maximum of 10 minutes only for their remarks.

ART. 8.—Members of Congress who desire to take part in the discussion of any Report may enter their names before the Congress by giving written notice to the General Secretary. During the Session they must communicate directly with the Secretary of the Section.

ART. 9.—Speakers will be called upon by the President according to the order of their inscription on the Agenda.

ART. 10.—Independent Papers. The afternoon Sessions will be devoted to the reading and discussion of independent papers. The titles of such papers ought to be announced to the Central Office of the Congress by the 30th of April, 1913 The Council of the Section has the right of selection from among the papers offered, and of declining any that they do not consider desirable. The Council of the Section will arrange the order in which the selected papers shall be read. Any papers offered after the 30th of April, 1913, will only be placed upon the agenda after the discussion of those which have been announced before this date and have been chosen by the Council of the Section. No paper will be accepted unless the text has been received by the Secretaries of the Section before the 1st of July, 1913. A maximum of fifteen minutes will be allowed for the reading of a paper, and five minutes for each speaker who takes part in the discussion. The author of the paper will be allowed five minutes for a reply.

ART. 11.—Speakers will receive two intimations from the President as to their time limit; notice will be given two minutes before, and at the moment of expiry of the period allowed.

ART. 12.—For certain communications of particular importance and general interest, the President may, with the consent of the Section, prolong by five or ten minutes the periods already indicated.

ART. 13.—If a speaker wanders from the subject under discussion, or indulges in personalities, the President may call upon him to sit down. If several members ask to speak upon a paper, and the hour is late, the President may on his own authority, or upon the proposition of a member, defer further discussion upon that paper to the end of the Session, if time permits.

ART 14.—The text of the remarks made in the course of discussions will only be inserted in the Transactions of the Congress if the speaker sends it in writing, condensed into 20 lines of print, to the Secretary of the Section before the end of the Session. (Block note-sheets will be placed for this purpose at the disposal of members by the Secretaries.) Those who omit to conform to this regulation will lose the right to have their remarks published in the Transactions.

ART. 15.—The Executive Committee reserves to itself the right to abridge the report of any discussion, and to omit any remarks of a personal character.

ART. 16.—Private resolutions can only be proposed after previous notice given to the President, and when the business on the Agenda has already been disposed of. For the proposal of any special resolution a maximum period of five minutes only will be allowed. The President will authorise only such resolutions as come within the limits of the work of the Section.

ART. 17.—No vote may be taken, nor any resolutions passed, upon questions of science or theory, but only on such questions as possess a practical or administrative character. On such questions the sense of the meeting will be taken by the majority standing or remaining seated. The President will transmit such resolutions as shall be passed, through the General Secretary, to the Permanent Commission of the Congress. The Commission will decide whether the resolutions in question ought, or ought not, to be put to the vote at the Closing Meeting of the Congress.

ART. 18.—The Secretaries of each Section will send an account of its transactions for the daily journal. This account will mention in chronological order the subjects of the Reports and discussions, the papers read, the names of the speakers, and any resolutions submitted to the Section.

and be pathognomonic in an otherwise obscure case of acute illness in childhood. Although all these conditions and their indications are known to many students preparing for examination as well as to practitioners, there is little doubt that they are not as generally applied as they should be. The ophthalmoscope is not a difficult instrument on which to acquire a sufficient facility for all ordinary purposes; the question of a suitable light is readily solved by any of the simple and cheap portable electric lamps now available, and in difficult cases dilatation of the pupil can quickly be obtained by a little homatropine. The opportunities given at hospitals and in post-graduate courses to learn the use of the ophthalmoscope are now abundant, and the time and trouble spent in this way are amply repaid.

THE PROGRESS OF SCHOOL HYGIENE IN PORTUGAL.

A CORRESPONDENT, writing from Lisbon, informs us that the Portuguese Government has determined on the medical inspection of superior upper schools and lyceums until such time as it shall be possible to extend the practice to all primary schools. Medical inspection is further about to be organised for certain private establishments. An important movement also, having for its aim the diffusion of new methods of education, which will result in considerable progress in both public and private teaching, is on the point of establishment. The Portuguese Society of Pædagogic Studies, founded Jan. 15th, 1910, has taken the lead in the movement for making known what are the scientific data and practical foundations of a sound educational system. As a beginning, the members of the society will hold a series of public conferences at which the following subjects will be discussed: the scientific basis of education; the psychology of the child; the medical inspection of schools; manual training in schools; sexual ethics; the struggle against alcoholism in the primary school; pædagogic methods; the coöperation of the family with the school in education; art in the school; children's gardens; interchange of school amenities; school fêtes and excursions. Next April a Congress of Pædagogy—the third in Portugal—organised by the National League for Instruction, will take place at Lisbon, and its second section will be devoted to school hygiene. The method of primary instruction will be entirely reformed on a plan to be established, on the proposition of Dr. Ladislau Piçarra, senator, after consultation with the Society of Pædagogic Studies.

ANCIENT HINDOO REMEDIES.

NERVOUS instability, amorousness, and mental fatigue would seem to be Hindoo characteristics, to judge by the newspaper announcements of the remedies of a certain Mr. Kaviraj Keshab Lall Roy. These are described as "some of the best specifics ever found out in the system of Ayurveda"—i.e., medicine. We ought, perhaps, to accept this statement as being made in good faith. There is, indeed, reason to suppose that the domestic medicine of Hindustan is still in the Vedic stage, and that a quack medicine in India is probably a traditional one, a descendant, indeed, of the pharmacopœia of the early Sanscrit philosophers. The ancient Hindoo pharmacy and therapeutics have of late years been illustrated by two notable publications. Of these, the first, published in 1905 by the University of Harvard, is Whitney's translation, with notes by Lanman, of the famous "Atharva-Veda." The second is the revised translation of the "Bower Manuscript" of the "Nâvanîtaka" (a Sanscrit work on medicine), published in 1909, under the editorship of Dr. Rudolf Hoernle, by the Archæological Survey of India. The Atharva-Veda is mainly concerned with prayers, incantations, and charms. The "Nâvanîtaka," on the other hand, is a vast handbook for the legitimate practitioner or for the self-medicating individual. It deals with diseases known to antiquity and chiefly prescribes vegetable remedies or simples, such as clarified butter. Thus chyavanaprâsa, or medicated ghee, so called after the famous sage Chyavana, is frequently referred to and perhaps reappears as the chyavanpras, recommended in cases of debility by Lall Roy. Impotence is for obvious reasons regarded as a particular calamity in the East, and thus we find an important section of the book devoted to aphrodisiacs, some of which are terrific enough. The medicine known as "the Sarasvati Clarified Butter" is for a Râjarshi who desires to beget a son. "Juice of Gôkshuraka (Tribulus terrestris), clarified butter, and milk of both a goat and a cow, together with one prasrita of honey, makes a prescription capacitating a man, &c." Another simple mixture, made into boluses, increases this capacity, and ensures "favouritism" among members of the other sex! Emblic myrobolan creates an erotic monster, and we are in the region of Orienal exaggeration with a vengeance. Signaturism plays a large part in the concoction of these mixtures. Thus "sparrow broth" and pig's fat are frequently recommended to the voluptuary, as also red rice, goat's milk, and the flesh of a cock. There is usually, however, some herbal ingredient, such as Ipomœa digitata, in any given medicine, which probably has a certain efficacy, even though it be only purgative.

THE CARE OF THE COMING RACE.

FEW public duties are of farther reaching importance than that of providing for the proper bringing up in sound health and adequate development of the future citizens of the Empire. While undoubtedly a considerable part of the present defective stamina of children, especially among the poorer classes, is due to unsatisfactory environment, quite a large part also is dependent on the ignorance of those on whose care the upbringing of the little ones devolves, an ignorance of how to make the most of those possibilities they possess, and how to ameliorate existing disadvantageous conditions. It was to combat this ignorance that the National League for Physical Education and Improvement was incorporated in 1905. Among the work done by this league was the establishment of infant consultation centres and of schools for mothers. During the past two years there has been a rapid increase in this work, and it is thought that the time has come for a further development of the organisation in relation thereto. We learn, accordingly, that it has been decided to form a special department to coördinate the work and to promote the formation of new centres. With this end in view, the Association of Infant Consultations and Schools for Mothers was inaugurated recently in a well-attended meeting, the chair being taken by Alderman Broadbent, of Huddersfield, whose name is so well known in relation to the cause of infant upbringing. At this meeting the constitution of the association was decided upon, and a strong provisional executive committee was formed to carry on the work until the first meeting of the representative general council can be held. The medical profession has accorded the movement generous countenance, and is to be represented on the governing bodies in equal numbers with non-medical delegates from the 34 affiliated societes. Alderman Broadbent, in his remarks, drew special attention to the happy combination of municipal and voluntary effort already effected in certain districts. The attention of the association is directed towards the establishment of a uniform method of keeping records and statistics, a necessary factor in all successful collaborative work. By this means, newly forming

societies can receive guidance and help to direct their efforts aright by the light of the failures and successes of their predecessors. All interested in the formation of societies of kindred aim can obtain valuable guidance by applying to the league at 4, Tavistock-square, London, W.C. There are now to be obtained from the league a leaflet of suggestions for the formation of consultation centres, medical case papers, and recording charts, while a series of coloured wall charts setting forth hygienic truths is in course of preparation. The first deals with the dangers of long-tube feeding-bottles. Others will pictorially demonstrate the dangers of unguarded fireplaces, the use of push carts, and similar matters. The stimulation of public interest in this subject is the function of the league, and the coördinating of the organisations that must necessarily result from such stimulus will be undertaken by the association. The work is surely worthy of support.

COLD ABSCESS OF THE ABDOMINAL WALL.

M. Savariaud opened a clinical lecture at the Trousseau Hospital recently by saying that the first thing essential to a correct diagnosis of certain morbid conditions is that the practitioner must be aware that such conditions do somel times exist. The remark is peculiarly apposite in relation to the relation between tuberculosis and primary cold abscess of the abdominal wall. Dr. Savariaud said that although tuberculosis is exhaustively studied, and so fully described in text-books, in its relation to most organs, there is general silence as to its occurrence in this position. Nevertheless, he has himself seen three cases in children within two years, and he quotes, in *La Semaine Médicale*, reports from other surgeons which bring the total number of recorded cases up to 21. Among these every age is represented. As a rule, the disease of the abdominal wall is not preceded by any other manifestation of tuberculosis. The abscess is most often situated laterally and rarely in the epigastric or umbilical regions; any of the various layers of the abdominal wall may be implicated, but the muscles and aponeuroses are the sites of election. The infection is usually blood borne, but it may reach the abdominal wall by the subperitoneal lymphatics, and M. Savariaud considers that it may begin as an invasion of the iliac lymph glands. The first symptom is pain, which, however, ceases as soon as the swelling has attained a certain size; it rarely becomes larger than an egg. It may have a solid consistence, or there may be a soft, fluctuating centre resting upon an indurated base. In either case it does not move with respiration, but hardens and disappears more or less completely during contraction of the abdominal muscles. The course of the disease is chronic, even exceeding a year in some instances. The possibilities of error in diagnosis are of two kinds: the swelling may be regarded as a new growth of the abdominal wall, or it may be mistaken for a lesion of the viscera within the abdomen. Indeed, in one of the cases reported by M. Savariaud the patient was thought to be suffering from cholecystitis up to the time of operation—in fact, until the first stages of the incision discovered pus in the abdominal wall itself. In these cases it is always necessary to take special care to exclude tuberculous lesions of the neighbouring bones (ribs, spine, pelvis), as spread of the infection from these may provoke the formation of intermuscular abscesses hardly distinguishable from those which arise primarily within the abdominal wall. The prognosis is good; open operation is nearly always successful in effecting a cure, the only troublesome sequelæ being fistulæ demanding further operative treatment and ventral hernia following the larger abscesses.

THE FEEBLE-MINDED AND THE LUNACY ACTS.

WE have received from the clerk to the guardians of Fulham a copy of a report by the workhouse visiting committee of that parish relative to the question of increasing the legal powers of compulsory detention of feeble-minded persons. The committee refer to the decision of the courts in the case of R. *v.* Shaw, as establishing the view that "imbecility and loss of mental power, whether arising from natural decay or from paralysis, softening of the brain or other natural causes, or intemperance, and though unaccompanied by frenzy or delusion of any kind, constitute unsoundness of mind amounting to lunacy" within the meaning of the Lunacy Acts. And they further quote the opinion of the Lunacy Commissioners, as stated in their reports for the years 1910 and 1911, to the effect that the powers conferred by Section 24 (3) of the Lunacy Act of 1890 would, if more liberally used, enable local authorities to certify and detain the weak-minded women and girls and the imbecile youths who have hitherto been allowed to live an in-an-out existence in the workhouses to their own detriment and with serious inconvenience and danger to the community. Accepting this view of the legal position, the committee deprecate the suggestion that there is any need to ask the legislature for further powers in order to deal effectively with these cases. While it is very gratifying to learn from this report that there are local bodies which take this broad view of their responsibilities, it must be borne in mind that the opinion which the Fulham guardians are putting forward has not hitherto been generally admitted, and it is tolerably certain that, even if it were recognised as sound in principle, it would be acted on by only a very small number of Poor-law authorities. Moreover, the insane wards of the workhouses, however admirably managed, are obviously unsuited for the permanent detention of the congenitally defective persons who form the large majority of the feeble-minded class. The continuous treatment with industrial occupation which these cases require can only be provided in institutions organised for their specific needs. While, therefore, it is eminently desirable that the fullest use should be made of the powers available under the existing law, it must be clearly understood that such powers are entirely inadequate to deal with the problem and that their value is merely that of a temporary expedient pending the adoption of a complete and thorough method for controlling this social evil.

THE Registrar-General desires to intimate to medical officers of health that they will be furnished about Feb. 1st with particulars of transferable deaths registered during the last quarter of 1911. At the same time will be supplied to them the numbers of births to be added to or deducted from those furnished them by registrars in order to correct for lying-in institutions in accordance with the announcement made in a footnote to Table I. of the Local Government Board. A copy of the Registrar-General's "Manual of Causes of Death" will, it is hoped, be sent to every medical officer of health during the latter part of the present month.

Dr. Sun Yat Sen, whose election to the Presidency of the new Republic of China is reported in the *Times*, studied medicine at Tientsin, and subsequently joined the staff of the Alice Memorial Hospital in Hong-Kong. Before engaging in politics he practised for a time in Canton.

THE Lord Chancellor has appointed Mr. Barnard Thornton Hodgson, barrister-at-law and secretary to the Commissioners in Lunacy, and Dr. Charles Hubert Bond, medical superintendent of the Long Grove County of London Lunatic

Asylum, to be Commissioners in Lunacy; and Mr. Oswald Eden Dickinson, barrister-at-law and secretary to the Lord Chancellor's Visitors in Lunacy, has been appointed, with the approval of the Lord Chancellor, secretary to the Commissioners in Lunacy, in the place of Mr. Hodgson appointed a Commissioner in Lunacy.

THE committee of organisation of the Seventh International Congress of Dermatology and Syphilography (Rome) has fixed as the date of the Congress April 8th–13th, 1912, immediately preceding the International Congress against Tuberculosis, which will take place on April 14th–20th. The final programme of the Congress of Dermatology will be printed during the latter half of the present month, and fresh communications can still be inserted up to Jan. 15th.

Mr. Robert Denman, M.R.C.S. Eng., L.S.A., D.P.H. Cantab., Director of the Medical and Health Department of Mauritius, has been nominated a Member of the Council of Government of the Colony of Mauritius.

WE regret to announce the death on Dec. 30th, 1911, at the age of 57, of Dr. John Francis Sutherland, Senior Deputy Commissioner in Lunacy for Scotland.

DONATIONS AND BEQUESTS. — The late Dr. Kershaw, formerly medical officer of health of Royton, has left his estate, of the value of £40,000, for hospital purposes for the town of Royton. It is proposed to erect a hospital at the estimated cost of £11,000 and an estimated upkeep of £2100 per annum. Under this scheme the hospital would have 30 beds, which would mean that the council would have to raise £1100 annually.—Under the will of the late Mr. John Roderick, of Staffordshire, the testator left £50,000 to the Birmingham General Hospital, £10,000 to the Queen's Hospital, Birmingham, £1000 to the Birmingham General Dispensary, and £1000 to the Birmingham Skin and Urinary Hospital. The estate duty on the property will absorb about £40,000, and after payment of this duty and the above bequests there will be a balance remaining of about £185,000, which will be reduced by payment of legacy duty at the rate of 10 per cent. on the various bequests to about £153,000, and this balance he left as to one-half to the Birmingham General Hospital, one-fourth to the Queen's Hospital, Birmingham, and one-fourth to the Birmingham General Dispensary.—The late Mr. Alfred John Heath, of Putney, has left the following legacies on the death of his mother:—A sum sufficient to endow a bed to be called "The Alfred and Clara Heath Bed" in each of the following hospitals: The London Hospital, the Middlesex Hospital, the Charing Cross Hospital, King's College Hospital, St. Mary's Hospital, Paddington, the Cancer Hospital, Fulham-road, S.W., and the Miller Hospital and Royal Kent Dispensary, Greenwich-road, S.E., and to the Hospital for Sick Children, Great Ormond-street, a sum sufficient to endow a cot to be called "The Cissy Cot," in memory of his sister, Clara Elizabeth Heath. All other his property he left to King Edward's Hospital Fund for London. The amount available for these charitable objects is about £17,000.—The late Mr. Joseph Withers has left by will £5000 to the Victoria Park Hospital, on condition that that hospital provides the mayor of the borough of West Ham with letters for the use of the poor.—The treasurers of the Middlesex Hospital have received a donation of 1000 guineas from Mr. J. D. Bland to endow a bed in memory of his wife.

PRESENTATION TO A MEDICAL PRACTITIONER.—Mr. Duncan R. Macdonald, L.R.C.P., L.R.C.S. Edin., has been presented by his friends and patients in Dunbar with a cheque for £348 for the purpose of purchasing a motor-car. This kindly act has been prompted by the desire of Mr. Macdonald's friends to conserve as much as possible his strength. The presentation was made in the parish church hall, Dunbar, on Dec. 27th, 1911, in the presence of a large and representative gathering of subscribers.

ON PULQUE AND PULQUE-DRINKING IN MEXICO.[1]

BY JOHN BLAND-SUTTON, F.R.C.S. ENG.,
SURGEON TO THE MIDDLESEX HOSPITAL.

THROUGHOUT the world men have discovered means for obtaining alcoholic beverages by the fermentation of starchy matter and saccharine juices obtained from the vegetable kingdom. The starch of cereals yields beer, whisky, and saké; from the juices of grapes, berries, apples, sugar-cane, pine-apples, bananas, and other fruits men obtain wine, brandy, cider, rum, and the like.

During a visit to Mexico I have had opportunities for studying pulque, an alcohol drink obtained from the fermentation of the sap of the maquey (Agave Mexicana).

The cultivation of this plant is an important industry on the Mexican tableland, and the maquey plantations are very extensive aud as numerous as cornfields in England. The maquey, or pulque-plant, is interesting as well as useful. When full grown it may be 10 feet high and possess 30 to 70 thick fleshy leaves arranged in rosette fashion on a stout fleshy stem, which is usually so short that the leaves appear to spring from the root. The leaves are thick, long, and terminate in a formidable spine, two inches or more in length, sharp and strong enough to penetrate leather. The edges of the leaves are armed with strong barbs, so that when a number of agaves are planted close together, the spiny armature of their leaves constitutes an impenetrable fence against man and beast.

The plant is propagated by means of shoots which spring from the roots of adult plants after flowering. These shoots are carefully planted in rows of about a hundred plants to the acre. The hole made for the reception of the plant is about a yard square and filled with good loose soil. In about seven years the maquey matures, and a single stalk or *mast* grows from the centre of the rosette, and may attain a height of 20 feet, and at the base it sometimes measures a foot in circumference. At a distance a flower column looks like a telegraph pole, and the upper end bears a huge pyramidal inflorescence not unlike a candelabrum, for it consists of branches carrying discs composed of hundreds of yellow flowers. These are in due course replaced by seeds, and as soon as the seeds ripen this enormous flower-stalk and the leaves die. Then shoots arise from the roots. Although the flower column or *mast* appears as bare as a telegraph pole, on close inspection rudimentary paper-like leaves will be found on it.

The maquey is trained to yield pulque in the following way. After planting it requires no attention until the flowering period, which happens between the seventh and tenth years; at this time the middle of the plant consists of a number of leaves closely compressed like the heart of a cabbage, but forming a sharply-pointed cone. An examination of the apex of this cone affords indications to the husbandman when a maquey is about to flower. The cone is then cut out, and the soft tissue at its base is scooped out of the short fleshy stem immediately above the root, leaving a cavity about six inches in diameter and four in depth. The soft tissue is scraped away by a scoop-shaped tool known as the raspador (Fig. 1, B). The removal of the central apical bud is called castration of the plant. The immature leaves from the cone are bright yellow, and after the cutting the husbandman sticks some of them on the spikes of the surrounding leaves to let the collector (tlachiquero) know that the plant has been cut. At the same time the edges of some of the leaves are stripped off to save him from being scratched (in spite of leathern clothes) by the lateral barbs when collecting the sap which oozes into the artificial cup scraped in the stem. A piece of leaf is usually placed over the hollow to keep out rain water, and on some farms the leaves are interwoven in such a way as to form a roof over it.

As soon as the plant is treated in this way the juice accumulates in the cavity, and twice daily a man or boy visits it and sucks up the fluid known as "aguamiel" (honey water) by means of the acocote. This instrument is a flask-shaped gourd from which the pulp has been extracted and the rind dried; at the narrow end a piece of an ox-horn

[1] A lecture delivered at the Middlesex Hospital.

is adjusted to serve as a spout, and the broad base of the gourd is perforated (Fig. 1, A).

This crude instrument is used in the following manner. The horn spout is introduced into the cup-like hole in the maquey and the man sucks the air from the gourd by applying his lips to the hole in the base; when the air is in this way withdrawn from the gourd the fluid rushes into it (Fig. 2). The aguamiel is then emptied from the acocote into a pigskin, which the man carries on his back or which is borne on the back of a donkey (Fig. 3).

After removing the fluid from the plant the man gently scrapes the cavity with his raspador. The scraping is a very necessary act in the management of the maquey; it comes about that each daily scraping enlarges the cavity in all directions, and in a large plant it may eventually have a capacity of 3 or 4 litres or more. If the scraping be carelessly or injudiciously performed the maquey quickly dies. A good plant well managed will yield 10 litres or more sap daily and furnish this amount for 20 weeks. As the plant fades, green shoots sprout from its roots in all directions and are in due course transplanted.

FIG. 1.

The implements of the tlachiquero for collecting the aguamiel from the maquey. A, The acocote made out of a gourd; its spout is a piece of ox-horn. B, The raspador or scraper. C, A piece of steel for sharpening the raspador.

The aguamiel as it exudes from the plant is a sweet, pale yellow fluid with a pleasant taste, and very attractive to insects. As soon as the tlachiquero has filled his pigskin he takes it to the hacienda, and the fluid—after being strained to free it from insects and chips of the agave—is poured into shallow receptacles made of ox-hide stretched on frames. In these it is allowed to ferment; this process is hastened by the addition of "madre" or mother pulque. The preparation of the madre requires care and experience, for the quality of the pulque depends in a large measure upon it. Fermentation proceeds so rapidly that it is complete within 24 hours; thus pulque cannot be transported in a condition fit for drinking beyond a journey of a few hours. When ready for consumption the pulque is placed in barrels and regularly conveyed in trains to Mexico city, in the same fashion that milk is brought to London daily in special trains.

The agave is useful to Mexicans in other ways than supplying pulque. An alcoholic extract known as mescal is distilled from its leaves and roots. Mescal is colourless, bitter, and possesses a peculiar aroma. It contains 20 per cent. of alcohol. Fibre from the leaves of the agave is used for rope-making and paper. The Aztecs used paper made from the finer kinds of fibre for writing and painting. The famous picture-writing was executed on paper of this kind. Agave leaves are used for thatching huts, and the stems and roots serve for firewood.

FIG. 2.

The tlachiquero collecting aguamiel from the maquey by means of the acocote. A pig-skin lies on the ground.

Pulque is a milky fluid with a specific gravity slightly less than water. Its milkiness is due to the presence of suspended particles and yeast cells; when these are precipitated by the centrifuge pulque becomes clear and transparent. According to O'Gorman and Allen, the species of yeast found in it are Saccharomyces cerevisiæ agavicia, S. ellipsoideus, Bacterium aceti, Bacillus viscosus, and B. acidi lactici can be obtained on cultivation. Pulque has a peculiar sour and offensive odour, resembling that of rotten eggs or cheese, or a combination of rotten eggs and sour milk.

The composition of pulque obtained by O'Gorman and Allen is the following (in parts per 1000): Solids, 17·90; alcohol, 44·50; volatile acid, 0·90; carbonic acid, 0·30; water, 936 40. The solid constituents consist of gum,

albuminoids, phosphoric acid, potash, phosphate of magnesia, and calcium.

The proportion of alcohol in pulque is a little less than that found in alcoholic drinks which come under the title of beer. For example, London porter contains 6 per cent. of alcohol; Munich lager beer, 5 per cent.; and pulque, 4·45 per cent.

The shops (pulquerias) where pulque is sold resemble in many points the old-fashioned beer-shops in England. They are easily detected by their odour, decorations, and groups of loungers. Pulque-shops, like beer-houses, have signs, some of which are picturesque, but the majority are gaudy. The walls may be painted with curious symbolic pictures replacing our old-fashioned sign-posts and in others the hangings consist of brightly coloured paper.

In relation to the pulque shops Flandrau, in his interesting book "Viva Mexico," refers to the constant amusement foreigners derive from reading their signs. "A foul little corner calcimined sky-blue with a life-sized lady reposing in a green bower painted on its finger-marked exterior is entitled El Nido de Amor, or a pink hole in the wall that can be seen for a block and smelled for two, is named Las Flores de Abril." Other and more appropriate names are El Infiernito (the little hell), La Seductoria, and Las Aves de la Noche (The Night Birds).

The names and signs of pulque shops appear to have an irresistible attraction for almost all who visit Mexico city. Many of the signs in use are those adopted by drinking-shops in London or any English town; among others, we find "The Three Graces," "The Gladiator," "Adam and Eve," "The White Rose," "The Toad in the Hole." One sign, "La Hermosa Xochitl" (Beautiful Flower), has an interest in relation to the discovery of pulque. It is believed that pulque was discovered in the latter half of the eleventh century by Papantzin, a kinsman of the Toltec king, Tepancaltzin. Papantzin sent his daughter Xochitl with a sample to the king, who appears to have been pleased with the fluid and charmed with the messenger, for he retained Xochitl and placed her in his harem. From their union a child was born and named Meconetzin, or Child of the Maquey. This legend is illustrated by a picture in the National Picture Gallery of Mexico, in which Xochitl is represented presenting a vessel of pulque to the king. (Fig. 4.)

FIG. 3.

Pig-skins on a donkey's back; they are filled with aguamiel.

FIG. 4.

Xochitl presenting pulque to the King.

It is a fact that the Aztecs were addicted to pulque-drinking at the time of the Spanish Conquest—1519. The Aztecs acquired it from the Toltecs. It is said that pulque-drinking led to the downfall of the Toltecs, for it caused them to neglect agriculture, in which they were proficient, and they became deficient in the art of war. Their decadence led to the loss of their possessions, for they were driven away by the first war-like tribe that came against them.

Pulque is described as the national drink of Mexico, and the Mexicans drink it as freely as English labourers, husbandmen, and artisans drink beer. It is not uncommon for a man to swallow five or six litres daily, and it is cheaper than beer, for it can be bought for 1*d.* a litre.

Pulque-drinking is chiefly confined to the working classes; men, women, children, and babies drink it freely, and with the same sociological and physiological effects which are the sequence of beer-drinking in England. Most of the acts of violence committed in Mexico city and Puebla—two cities in the centre of the pulque industry—are attributed to pulque drunkenness. The fact that pulque cannot be exported limits its sphere of influence; in order to supply the drinkers special trains convey the fluid to the cities, and when a fresh supply is delivered at the shops the fact is announced for the benefit of the customers, as in a German beer garden the bier-kellner shouts *wird gezapft* to inform the guests that he is about to tap a fresh barrel. Many unsuccessful attempts were made to abolish the traffic in pulque by the Spanish viceroys and archbishops during the seventeenth century. In 1692 an edict for this purpose led to a formidable riot; the archbishop's palace was stoned and an infuriated mob set fire to several public buildings. The Mexican peons are so devoted to pulque that they regard it as a "liquor divine, which angels in Heaven prefer to wine." Pulque shops are under the control of the law and are closed at 6 o'clock. In times of political excitement these shops are closed for the safety of the city. Taken in moderate quantity the drink produces excitement; the drinkers then become quarrelsome and dangerous. Intoxication produced by a large quantity is followed by heavy sleep. The effects of excessive pulque-drinking on the system

have been carefully studied, and they appear to be such as are seen in the habitual drunkard in Europe. Aguamiel has been used as a remedy for inflammatory conditions of the urinary organ by Mexican physicians for centuries. To-day American physicians send patients with Bright's disease to take an aguamiel cure in Mexico. The aguamiel obtained from the maqueys plain of Apam has the greatest reputation.

The pulque industry to-day is mainly in the hands of a powerful trust company, and though the abolition of pulque-drinking is impossible it can be in a measure controlled. This company has initiated scientific investigations to ensure cleanliness in its manufacture and with the object of depriving the fluid of some of its deleterious products. In this way pulque will be rendered more wholesome and its production placed on a scientific basis like beer-brewing in England.

Brook-street, W.

MEDICINE AND THE LAW.

Culvert Gases: Carbon Monoxide or Sewer Gas?

Mr. Justice Lush recently heard a case in which there were raised questions of very great interest both to scientists and medical jurists. The Rochdale corporation sued the trustees of the Rochdale Markets Company in the following circumstances. On the morning of June 6th, 1910, three men, named Harris, Clegg, and Collins, were engaged in the construction of a culvert. After they had been in the culvert for about an hour Harris came up and said, "It was rather strong down there." The other men also came up and were told not to go down again. Harris died at 6 o'clock, after being taken home in a cab. Clegg also died, and Collins, after a severe illness, recovered. It was alleged that the men had been what is called "gassed." The plaintiffs paid compensation, which they now sought to recover, on the ground that the men had been poisoned by carbonic oxide and other noxious fumes which had been conveyed into the culvert by a pipe connected with a gas engine used by the defendants. Dr. A. G. Anderson, medical officer of Rochdale, was of opinion as a result of a post-mortem examination that the death of Harris was caused by the inhalation of a dangerous quantity of carbon monoxide, though that was not the full explanation, because there was evidence that he had inhaled some other noxious gas. The condition of the lungs denoted the presence of other gases. He failed to discover any trace of sulphuretted hydrogen. Dr. H. S. Heap found a large amount of carbon dioxide and also some carbon monoxide in the culvert. He knew of nothing except carbon monoxide which could produce the cherry red appearance of the blood, which he found was saturated with from 12 to 15 per cent. of carbon monoxide. Professor S. Delépine, after experimenting with gas engines of a similar make to that used by the defendants, said that the symptoms suggested poisoning by irritant gases as well as by carbon monoxide. Sulphuretted hydrogen had nothing to do with causing the deaths. In his opinion death was due to the combined effects of the carbon monoxide and such gases as might be emitted by a gas engine. The defence submitted that no case of negligence had been made out, and it was further submitted that the plaintiffs had been guilty of contributory negligence, as they knew that the defendants turned the gas from the exhaust pipe into the culvert and sewer, and yet allowed their workmen to go into that which they now charged against the defendants as a death chamber. The blood drawn from the man who recovered, according to Dr. W. Ross, showed absolutely no indication of carbon-monoxide poisoning. Dr. J. S. Haldane, of Oxford, said he thought the cause of death was poisoning by sulphuretted hydrogen, and that carbon monoxide had nothing to do with it. In his experience of carbon-monoxide poisoning it was unknown that persons who had died from that cause had been able to walk about after being "gassed"; yet in this case the men climbed out of the manhole without assistance, went to breakfast, and were considering about doing another piece of work. Dr. F. Craven Moore corroborated the view of Dr. Haldane. The judge said he had to reconcile two almost irreconcilable themes advanced by eminent men. Judgment was reserved.

The Case of Charles Louis Lumley.

At the last sessions at the Old Bailey a man named Charles Louis Lumley was tried for the murder of a woman named Gorringe through the performance of an illegal operation upon her. Gorringe was a married woman living apart from her husband and employed as a draper's assistant. She had been with a man with whom she had cohabited to consult Lumley, who was formerly upon the Medical Register, but whose name had been removed in 1900 on a charge of a different character from that upon which he has now been convicted. Mrs. Gorringe became very ill and died, the medical evidence being directed to proving this to be the result of an attempt to procure miscarriage, the only question being whether what had taken place had been the act of the woman herself or of someone else, before she visited Lumley. The prisoner protested his innocence throughout, saying that the woman had been very ill when she came to him, and that he had done the best he could for her. The jury convicted him of manslaughter, and the police gave evidence to the effect that although he had never been before charged he had long been an object of suspicion, and that patients whom he had attended had died on previous occasions when there had been reason to believe that they had been the victims of illegal operations. Mr. Justice Avory, in passing a sentence of seven years' penal servitude, told the prisoner that it was only by a lenient interpretation of the facts that he had not been convicted of murder, and that the evidence showed him to have been perfectly ready to adopt the course which he undoubtedly did adopt with regard to Gorringe.

Revolvers Again.

In THE LANCET of Oct. 21st, 1911, p. 1144, reference was made to the trial then pending of a gang of ruffians, many of them habitually armed with revolvers, whose violence had culminated in acts which had led to their arrest. They were tried at the Old Bailey before Mr. Justice Avory with the result that four were convicted of inflicting grievous bodily harm upon a man with whom they had quarrelled, and whom they attacked chiefly with broken glass as a weapon, one of shooting at a person unknown, one who pleaded guilty of an assault, and two, also pleading guilty, of being concerned in a riot. All received long sentences of imprisonment with hard labour, to which penal servitude for three years was added in two instances, and the man convicted of shooting received a sentence of three years' penal servitude. In one of their fights among themselves a lad not connected with their quarrel had been severely injured. At the conclusion of the trial Mr. Justice Avory, whose experience of the revelations of criminal trials is second to none, made the following comment: "I wish to say before I leave this case that the condition of things disclosed by this evidence, that a portion of London should be infested by a number of criminal ruffians armed with loaded revolvers, is a state of things which ought not to be further tolerated, and if the existing law is not strong enough to put a stop to it, some remedial legislation is necessary." THE LANCET has protested for many years against the unrestricted sale, and unhindered carrying, of pistols, which are now far more dangerous weapons and much easier to obtain as such for a small price than they were 10 or 20 years ago. It should be made a serious offence to carry such a weapon on the person in any public place or to possess one without a licence. This should not be obtainable without close investigation of the applicant's character and of the uses to which he is likely to put it, and a heavy duty, to be remitted where remission is desirable, should further restrict the sale of such weapons. In support of these views we may point out that another prosecution for carrying a loaded revolver without a licence has taken place. We hope that Mr. Denman's weighty plea for effective legislation against this evil, then made, will not fall on deaf ears.

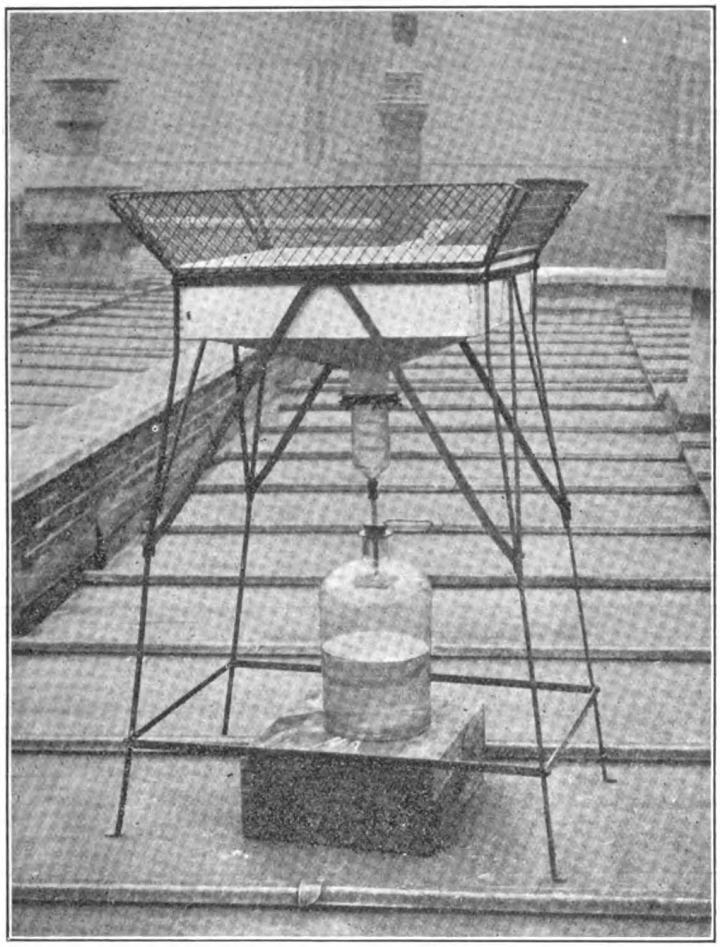
Dr. R. Murray Leslie, senior physician to the Prince of Wales General Hospital, Tottenham, has been specially presented by the French Consul-General to M. Cambon, the French Ambassador, who personally conferred upon Dr. Leslie the decoration of Officier de l'Instruction Publique et des Beaux-Arts, recently awarded to him by the French Government.

THE SOOTFALL OF LONDON:

ITS AMOUNT, QUALITY, AND EFFECTS.

AN APPEAL FOR SOOT-GAUGE OBSERVATIONS.

THE positive readings of the soot-gauge disclose the defects of the coal fire. The black carbonaceous deposit is an evidence of faulty combustion and wastage of fuel; it means also the emission of products injurious to health, corroding to building fabrics, and often enough opaque in the aggregate to the sun's radiations, so reducing day to the darkness of night. The revelations of the soot-gauge are therefore of the utmost significance in regard to public health, comfort, and convenience. In great towns and cities an importance might reasonably be attached to the regular recording of sootfall equal to that of rainfall, but the soot-gauge so far has not been included amongst the instruments at the stations where meteorological observations are made. The present investigation shows that such observations would be valuable, and their record would most probably lend the greatest assistance to the pleadings for a clean, unsullied air. At present the readings of the soot-gauge merely prove the existence of a serious evil amongst us, and also that there is every reason why this evil should receive regular registration and treatment. It is to be hoped that the time will come, however, when the soot-gauge will be an entirely superfluous instrument as an auxiliary in weather observing stations, an obsolete apparatus the use of which would be ludicrous in improved conditions. The following account of some observations made in this direction shows, however, that that fortunate time is not now.



The soot-gauge on a roof in Westminster.

A JUSTIFICATION FOR THE APPEAL

In the early part of 1910 Dr. H. A. Des Vœux, honorary treasurer of the Coal Smoke Abatement Society, and Dr. J. S. Owens, A.M.I.C.E., consulted our Laboratory Commissioners in regard to making some experiments in the direction of estimating the matters deposited from London atmosphere at regular intervals over a period of a year at various stations in the metropolitan area. A scheme was eventually formulated and the first serious experimental observations were made on June 13th, 1910. Three stations in London were chosen: A, situated in Buckingham Gate, S.W.; B, situated in Horseferry-road, S.W.; and C, in Old-street, City. To these a station, D, on the borders of the metropolitan area at Sutton, Surrey, was added, which it was thought would furnish results enabling an interesting comparison to be made with the results obtained at the foregoing stations. The apparatus employed to catch the deposit is shown in the accompanying illustration which is reproduced from a photograph. It represents a kind of hopper or wide funnel measuring at the top 2 feet square, terminating in a narrow tube below, connected with a capacious bottle. At first the plan consisted in using glass wool filters to keep back the deposit, but the rain percolating these filters was found to reduce their original weight considerably, and so it was decided to catch both rain and deposit without the intervention of a filter in the same apparatus and separate them subsequently by filtration in the laboratory. It is obvious that in the event of rain occurring the deposit collected would yield up its soluble parts to the rain water, and so whatever its original weight may have been it would fail to be recorded if a filter were used. The bottle containing the rain and the collected deposit were sent as far as could be conveniently arranged at intervals of a month to THE LANCET Laboratory for examination. The interval July 14th to July 28th was a shortened one owing to a heavy fall of rain. The observations lasted over a period of a year, commencing on June 13th, 1910, and ending June 13th, 1911. One or two irregular periods could not be avoided, but the totals represent an accurate period of one year's fall. In one case, however, an observation was prevented from being made through an accident to the bottle. This was at Sutton, Surrey, during the period November – December, 1910, so that the total deposit recorded for that station is for 11 months instead of 12, as applies to all other cases.

The table speaks for itself, and the results will repay a detailed study. The observations during each month are summarised for the year in the last four lines of the table, and a calculation based on the local experiments made appears in the last column but one, giving some idea as to the enormous deposit that probably occurs over the entire administrative area (117 square miles) of the County of London during a month and the total for a whole year respectively.

A SUMMARY OF THE RESULTS.

Summarised, the results, as indicated in the table, are as follows:—

Total deposit.—This is greatest in the City area, amounting to about 650 tons per square mile per year. In the S.W. district the average amount was 460 tons per square mile per year, while on the same calculation the fall immediately outside the metropolitan area was 195 tons per square mile per year. The maximum fall in the City district was in the period October–November when there were local fogs; the maximum fall in the S.W. district was in July–September, but the deposit contained autumn leaves. Without leaves

* This sample was lost owing to the breaking of the bottle. The results under "total for the year" represent therefore the deposit of 11 months in the case of the sample from Sutton.

the maximum deposit in the S.W. district was in October–November when local fogs occurred. The maximum deposit in the area just outside the metropolis was in the autumn months and December–January period.

The minimum fall of total deposit in the City area was in the period between Sept. 6th and Oct. 1st; in the S.W. district the minimum fall was in September; in the area just outside the metropolis the minimum fall was in July and between January and February, in spite of fogs during the last period.

Insoluble deposit (soot, &c.).—The greatest amount of insoluble deposit (soot, &c.) fell in the City between Oct. 1st and Nov. 1st and Jan. 12th and Feb. 12th when fogs were prevalent; the smallest fall was between September and October. In the S.W. district the insoluble deposit, on the whole, was less than that which fell in the City district, the maximum fall being in the period January–February, and the minimum in the period September–October. In the suburban district (Sutton) the fall of insoluble deposit (soot, &c.) was about a sixth of that falling in the metropolitan area, the maximum fall being, curiously enough, in the summer months, May, June, July, while the minimum fall occurred in the period January to February.

Soluble matters contained in the rain.—The soluble matters comprise ammonium and calcium salts, sulphates and chlorides, and some organic constituents. On the year's showing the City area leads again in regard to the amount of dissolved solids, the maximum amount occurring in the period October–November and December–January, the minimum appearing in September.

In the S.W. district the maximum soluble matters appeared in December and the minimum in the summer months. In the suburban district (Sutton) the soluble matters in the rain amounted in the year to about three-fourths the quantity found in the metropolitan area, the maximum fall being in July and the minimum in January, which is exactly the reverse of the metropolitan occurrences.

Soluble volatile solids.—These include ammonium salts and organic matters. The E.C. and S.W. districts were about level in regard to the amounts of soluble volatile solids contained in the falling rain. The maximum in the City district occurred in August and October, the minimum in June and September, while in the S.W. district the maximum occurred also in August (heavy rains), and the minimum in June and September (a dry period). In the suburban district the total amount of soluble volatile solids was much the same as that falling in the metropolitan area, the maximum appearing in August and the minimum in January and June.

Soluble fixed solids.—These include common salt and sulphate of lime. The fall in the City area was greatest, and in the suburban area least, the amount in the S.W. district lying between the two. The maximum fall in the City area occurred in October and the minimum in the preceding month, September. In the S.W. district the maximum occurred in October and December, and the minimum in September. In the suburban district the maximum also occurred in October, but the minimum appeared in March–April.

Sulphate.—The figures in this column are of particular interest, inasmuch as most, if not all, of the sulphur found in the rain may be traced to the combustion of coal and gas. The City area receives a much larger amount of sulphates than the S.W. district—nearly double as much; while in the suburban area there were occasions when sulphates were present only in traces or were not present at all. The maximum fall in the case of the City area occurred in October, November, and December, when there was fog, while the minimum amount was in September and generally in the summer months. In the S.W. district the maximum occurred in the same autumn and winter period, and the minimum again in the summer months. In the suburban district the maximum fall of sulphate occurred in December, while there were only traces present when elsewhere the fall was considerable.

Ammonia.—This is an interesting column, because ammonia is a product of the faulty combustion of coal, while coal gas, which is free from ammonia, yields none on combustion, even when this has been imperfect. The City area again receives the largest amount of ammonia in the rainfall; the S.W. district comes next with about three-fourths the quantity, while in the suburban area over the year the amount was about 1-20th of that which fell in the metropolis. The maximum fall in the city district occurred in March–April, when there were snow showers, but the figure was also high in the foggy period, November–December. The minimum occurred in September. In the S.W. district the results were much the same, while in the suburban district on eight occasions the amount of ammonia was inappreciable, even when there was snow. The purifying effect of snow upon the air has been practically demonstrated by analyses made of London's snow fall in THE LANCET Laboratory on several occasions (*vide* THE LANCET, Jan. 5th, 1907, and Jan. 2nd and March 6th, 1909).

It is interesting to note that as a rule the rain water falling in the metropolis is scarcely ever acid, in spite of its load of impurities. This point is of some importance since it is generally reported in regard to the rainfall of provincial cities such as Manchester, Leeds, and Glasgow that the water is invariably acid. London has no foundries, chemical works, or large power installations comparable with these places, and the inference is that the domestic coal fire keeps the rainfall of London neutral, or if anything slightly alkaline, with the ammoniacal tarry compounds of the smoke. In large manufacturing towns the blast furnaces of industry, in which the fuel is more or less completely burnt, swamp the alkalinity of the domestic fire with their acid emanations. Turning again to domestic heating, if gas were entirely substituted for coal in London the rain probably would be no longer neutral or slightly alkaline, but acid, because ammonia would then no longer be evolved from the domestic fire. This is an advantage in considering the effects of the soot-fall, a point on which there will be much more to say. It is not improbable that the presence of ammonium salts encourages rather than discourages the disintegration of building fabrics, since insoluble lime compounds—e.g., calcium carbonate—readily yield ammonium carbonate and soluble calcium sulphate, and ammonium carbonate attacks silica. Free sulphuric acid would also attack lime compounds, but would not affect the silica appreciably.

Chlorine in chlorides.—The presence of chlorides in the rainfall in London is a mystery. Both coal and gas are, at all events, free from chlorides. The amount in the London atmosphere is greatest during foggy or snowy weather, and the quantity washed out by the snow or rain or deposited moisture is much the same at the different stations. In the suburban districts the quantity through the year was about half that found at the metropolitan stations. Proximity to the sea, of course, accounts for an increased amount of chloride in seaside air, but in these experiments the amount was greater in the City and S.W. districts than it was in the suburban district (Sutton, Surrey), which is in a seawards direction from London.

Lime.—The presence of lime may be accounted for in the dust from building fabrics and in the ash of coal. It is present as sulphate in the rainfall, and sulphate of lime is a constituent of coal ash, but it is conceivable that ordinary carbonate of lime is the original constituent in the rain- and soot-fall, the carbonate being converted into soluble sulphate by interaction with the ammonia and sulphur in coal smoke. By an oversight the search for lime salt was only made on three occasions. It occurred in the greatest amount in the deposit taken from the City station, but it is interesting to note that there was more lime in the deposit at Sutton, Surrey, than at the S.W. stations in the metropolis.

THE QUANTITY AND QUALITY OF LONDON SOOTFALL SUMMED UP.

The last column of figures in the table deals with some stupendous facts. If we take the City station as the basis of our calculation as to the total amount of deposit falling annually upon the Administrative County of London, including the City, which is 117 square miles, this deposit amounts to no less than 76,050 tons, in which are present over 6000 tons of ammonia (NH_3), 8000 tons of sulphate (SO_4), 3000 tons of chlorine in chlorides, to say nothing of the carbon and tar.

If we take the S.W. metropolitan station as a basis the total deposit per year over the same administrative area would average 53,820 tons, in which are present over 4000 tons of ammonia (NH_3), about 5000 tons of sulphate (SO_4), and 4000 tons of chlorine in chlorides. The London rainfall in foggy seasons is also distinctly destructive to metal surfaces,

as decided traces of tin and lead were found in the specimens examined.

According to other figures in the table which refer to the suburban area the man who lives there would appear to enjoy something approaching an immunity from this appalling downpour of chemical substances.

Simultaneously with the inquiry respecting the soot-fall an investigation has been in progress to determine the nature of the deterioration of building stone, and to ascertain, quantitatively, the influence of the soot-fall in this direction. A number of difficulties have presented themselves at various stages of the inquiry, and although some valuable information has been obtained it is not considered sufficiently conclusive to justify any safe general inferences being made for the present.

VITAL STATISTICS.

HEALTH OF ENGLISH TOWNS.

IN 77 of the largest English towns, having an estimated population of 16,157,797 persons in the middle of the year 1911, 7795 births and 4911 deaths were registered during the week ending Dec. 23rd. The annual rate of mortality in these towns, which had been 15·7, 15·2, and 16·4 in the three preceding weeks, declined to 15·9 per 1000 in the week under notice. During the first twelve weeks of the past quarter the mean annual rate of mortality in these towns averaged 14·6 per 1000, and was 0·3 per 1000 above that recorded in London during the same period. The annual death-rates in the 77 towns in the week under notice ranged from 7·6 in Devonport, 7·9 in Bournemouth, 9·7 in Willesden, and 10·6 in Ipswich, to 23·0 in Burnley, 23·1 in Stoke-on-Trent, 24·0 in Bury, and 24·4 in Stockport.

The 4911 deaths from all causes in the 77 towns in the week under notice were 172 fewer than the number in the previous week, and included 291 which were referred to the principal epidemic diseases, against 238 and 305 in the two preceding weeks. Of these 291 deaths, 70 resulted from measles, 67 from diphtheria, 55 from infantile diarrhœa, 52 from whooping-cough, 25 from scarlet fever, and 22 from enteric fever, but not one from small-pox. The mean annual death-rate from these epidemic diseases was equal to 0·9 per 1000, against 0·8 and 1·0 in the two previous weeks.

The deaths attributed to measles, which had been 66, 52, and 71 in the three previous weeks, numbered 70 in the week under notice, and caused the highest annual death-rates of 1·4 in Stockport, 1·5 in Smethwick, 1·7 in Walsall, 2·2 in Nottingham, 2·4 in Burnley, 2·5 in Oldham, and 2·6 in Norwich. The deaths referred to diphtheria, which had been 57, 60, and 64 in the three previous weeks, further rose to 67, and included 24 in London and its suburban districts, 7 in Leeds, and 3 in Plymouth. The fatal cases of infantile diarrhœa, which had been 68, 45, and 68 in the three preceding weeks, declined to 55, and of this number 20 were recorded in London and its suburban districts, 4 in Manchester, and 3 in Wigan. The deaths attributed to whooping-cough, which had steadily risen from 16 to 53 in the seven preceding weeks, numbered 52; 9 deaths occurred in London, 6 in Birmingham, and 3 each in Portsmouth, Walsall, and Leicester. The deaths referred to scarlet fever, which had been 16 and 27 in the two preceding weeks, slightly declined to 25, and included 4 in Norwich, and 2 each in London, Birmingham, Manchester, Leeds, and Newport (Mon.). The 22 fatal cases of enteric fever were equal to the average in the six preceding weeks; 3 deaths were recorded in London, 3 in Sheffield, and 2 each in Manchester, Salford, and Rotherham.

The number of scarlet fever patients under treatment in the Metropolitan Asylums and in the London Fever Hospital, which had decreased from 2213 to 2041 at the end of the five preceding weeks, had further declined to 1912 on Saturday, Dec. 23rd, 1911; 182 new cases of this disease were admitted to these institutions during the week, against 248, 241, and 224 in the three preceding weeks. These hospitals also contained on Saturday, Dec 23rd, 1311 cases of diphtheria, 227 of whooping-cough, 90 of measles, and 71 of enteric fever, but not one of small-pox. The 1363 deaths from all causes in London were 27 fewer than the number in the previous week, and included 390 which were referred to diseases of the respiratory system, against numbers steadily increasing from 170 to 391 in the seven preceding weeks.

The deaths attributed to different forms of violence in the 77 towns, which had been 201 and 195 in the two previous weeks, further declined to 185, and 431 inquest cases were registered. The causes of 47, or 1·0 per cent., of the deaths registered in the 77 towns were not certified either by a registered medical practitioner or by a coroner after inquest. All the causes of death were duly certified in Manchester, Sheffield, Leeds, Bristol, West Ham, Bradford, Hull, Newcastle-on-Tyne, and in 41 other smaller towns. The 47 uncertified causes of death included 11 in Birmingham, 4 in Stoke-on-Trent, and 2 each in London, Warrington, Blackburn, Rotherham, Gateshead, and Swansea.

HEALTH OF SCOTCH TOWNS.

In eight of the principal Scotch towns, having an estimated population of 1,710,291 persons in the middle of the year 1911, 809 births and 609 deaths were registered during the week ending Dec. 23rd. The annual rate of mortality in these towns, which had been 16·8 and 17·9 in the two preceding weeks, further rose to 18·6 per 1000 in the week under notice. During the first twelve weeks of the past quarter the mean annual death-rate in these Scotch towns averaged 16·9, and was 2·3 per 1000 above the mean rate during the same period in the large English towns. The annual death-rates in the several Scotch towns during the week under notice ranged from 13·1 and 15·4 in Perth and Paisley to 22·0 in Aberdeen and 25·6 in Greenock.

The 609 deaths from all causes were 22 in excess of the number in the previous week, and included 69 which were referred to the principal epidemic diseases, against 58 and 59 in the two preceding weeks; of these 69 deaths, 38 resulted from measles, 10 from diarrhœal diseases, 10 from whooping-cough, 7 from diphtheria, 3 from scarlet fever, and 1 from enteric fever, but not one from small-pox. The mean annual death-rate from these epidemic diseases was equal to 2·1 per 1000, and was 1·2 per 1000 above the mean rate from the same diseases in the 77 large English towns. The deaths referred to measles, which had been 31, 23, and 32 in the three preceding weeks, further rose to 38, and comprised 25 in Glasgow, 8 in Aberdeen, 3 in Edinburgh, and 2 in Greenock. The deaths attributed to diarrhœal diseases, which had steadily declined from 19 to 8 in the five preceding weeks, slightly rose to 10, and included 8 of infants under two years of age; 5 deaths were registered in Glasgow and 2 in Aberdeen. The 10 fatal cases of whooping-cough were 2 in excess of the average in the three preceding weeks, and included 5 in Glasgow and 3 in Aberdeen. The deaths referred to diphtheria numbered 7, against numbers declining from 15 to 6 in the three previous weeks, and included 3 in Leith and 2 in Dundee. The 3 fatal cases of scarlet fever were equal to the average in the three preceding weeks; the death from enteric fever occurred in Glasgow.

The deaths referred to diseases of the respiratory system, which had increased from 113 to 126 in the four preceding weeks, declined to 118, but were 1 in excess of the number recorded in the corresponding week of 1910. Of the 609 deaths from all causes in the Scotch towns during the week under notice, 157, or 26 per cent., were recorded in public institutions, and 24 were attributed to different forms of violence. The causes of 15, or 2·5 per cent., of the deaths in the eight towns were not specified or not certified; in the 77 large English towns the proportion of uncertified causes did not exceed 1·0 per cent.

HEALTH OF IRISH TOWNS.

In the 22 town districts of Ireland, having an estimated population of 1,149,495 persons in the middle of the year 1911, 490 births and 401 deaths were registered during the week ending Dec 23rd. The annual rate of mortality in these towns, which had been 17·7 and 20·9 in the two preceding weeks, declined to 18·2 per 1000 in the week under notice. During the first 12 weeks of the past quarter the mean annual rate of mortality in these towns averaged 18·5 per 1000; in the 77 large English towns the mean annual death-rate during the same period did not exceed 14·6, while in the eight Scotch towns it was equal to 16·9 per 1000. The annual death-rates during the week under notice were equal to

19·9 in Dublin (against 15·7 in London), 18·1 in Belfast, 22·5 in Cork, 11·5 in Londonderry, 13·6 in Limerick, and 5·7 in Waterford; while in the 16 smallest of these Irish towns the death-rate did not exceed 17·2 per 1000.

The 401 deaths from all causes were 60 fewer than the number in the previous week, and included 39 which were referred to the principal epidemic diseases, against 25 and 35 in the two preceding weeks; of these 39 deaths, 16 resulted from whooping-cough, 9 from diphtheria, 6 from measles, 4 from scarlet fever, and 4 from diarrhœa, but not one from enteric fever or from small-pox. These 39 deaths from the principal epidemic diseases were equal to an annual death-rate of 1·8 per 1000; in the 77 English towns during the week under notice the mean annual death-rate from these diseases did not exceed 0·9, while in the eight Scotch towns it rose to 2·1 per 1000. The deaths attributed to whooping-cough, which had declined from 11 to 6 in the four preceding weeks, rose to 16, and included 8 in Belfast, 5 in Dublin, and 2 in Lurgan. The deaths referred to diphtheria, which had been 4 and 5 in the two previous weeks, rose to 9, of which 5 were registered in Dublin and 2 in Belfast. The 6 fatal cases of measles, of which 4 occurred in Dublin, were one less than in the previous week. The deaths referred to diarrhœal diseases, which had been 7 and 13 in the two preceding weeks, declined to 4, all of which related to infants under two years of age; 2 deaths were recorded in Dublin. Three of the 4 fatal cases of scarlet fever were registered in Dublin.

The deaths referred to diseases of the respiratory system, which had increased from 77 to 105 in the three preceding weeks, declined to 83. Of the 401 deaths from all causes in the Irish towns 145, or 36 per cent., were recorded in public institutions, and 9 were attributed to different forms of violence. The causes of 19, or 4·7 per cent., of the deaths in the 22 towns during the week were not certified either by a registered medical practitioner or by a coroner after inquest; the proportion of uncertified causes in the 77 English towns did not exceed 1·0 per cent., while in the eight Scotch towns it amounted to 2·5 per cent.

THE SERVICES.

ROYAL NAVY MEDICAL SERVICE.

THE following appointments have been notified:—Staff-Surgeons: R. S. G. T. Bond to the *Melpomene*, on recommissioning; A. K. Smith-Shand to the *President*, additional, for three months' special course at metropolitan hospitals, on the return of the *Natal* to England. Surgeon: Q. H. Richardson to the *Natal*, on return to England.

ROYAL ARMY MEDICAL CORPS.

Surgeon-General A. T. Sloggett, C.B., C.M.G., principal medical officer of the Sixth (Poona) Division, has been selected for appointment as Principal Medical Officer of His Majesty's Forces in India (vice Surgeon-General Sir F. W. Trevor, K.C.S.I., C.B.). Lieutenant-Colonel L. T. M. Nash, on return from Karachi, has been appointed to the medical charge at Hounslow, vice Lieutenant-Colonel C. A. Lane, who has been detailed for a tour of service with the Southern Army in India. Lieutenant-Colonel T. B. Winter has been selected for appointment as officer in charge of the Military Hospital at Colchester, and to command No. 9 Company of the Royal Army Medical Corps, vice Lieutenant-Colonel F. H. M. Burton, transferred to Warley. Lieutenant-Colonel N. Manders, on return from Ceylon, has been posted to the Curragh with a view of replacing Lieutenant-Colonel G. F. Gubbin, who is about to retire. Lieutenant-Colonel J. M. F. Shine, at present commanding the Military Hospital at Fyzabad, has been selected for the higher rate of pay under Article 317 of the Royal Warrant. Lieutenant-Colonel T. McCulloch, on return from Calcutta, has been appointed to hold charge of the Medical Division, Royal Victoria Hospital, Netley. Lieutenant-Colonel E. A. Burnside has embarked for a tour of service in India for duty in the Ninth (Secunderabad) Division.

Major F. E. Gunter has been appointed Specialist in Advanced Operative Surgery to the Eighth (Lucknow) Division. Major W. T. Mould, from the Military Hospital at Dover, and Major J. M. Sloan, D.S.O., adjutant of the Royal Army Medical Corps School of Instruction at Aberdeen, have embarked for a tour of service in India. Major L. F. Smith has been appointed to command the Station Hospital at Nowshera. Major H. Herrick has taken up the command of the Military Hospital at Naini Tal. Major A. A. Seeds, at present doing duty at the Military Hospital at Hounslow, has been placed under orders to embark next February for a tour of service in the Second (Rawal Pindi) Division of the Northern Army in India.

Captain R. H. MacNichol, from the military hospital at Colchester, has been selected for appointment as Specialist in Dermatology and Venereal Diseases to the Royal Herbert Hospital at Woolwich. Captain S. M. W. Meadows has taken over charge of the Military Families Hospital at Tidworth, in succession to Captain R. V. Cowey. Captain O. Ievers, on return from a tour of service at Wynberg, South Africa, has been ordered to join in Ireland for duty and will be posted to the Dublin District. Captain V. H. Symons, from Bloemfontein, has been appointed to the Belfast District. Captain J. J. O'Keefe has been appointed to hold Civil Medical Charge at Roorkee in addition to his duties at the station hospital. Captain R. E. Humphrey, from Jhansi, and Captain W. Benson, in charge of the Cantonment Hospital at Rawal Pindi, have been placed on duty with troops proceeding from Bombay on board the transport s.s. *Plassy* on Jan. 11th for Southampton. Captain R. G. H. Tate has been selected for appointment as Sanitary Officer of the Third (Lahore) Division. Captain R. H. Bridges has taken up duty at Manchester as Adjutant of the Royal Army Medical Corps School of Instruction to the East Lancashire Division in succession to Major L. Wood, whose tenure of the appointment has expired. Captain G. E. Ferguson, on return from duty in Cyprus, has been appointed to the Southern Command. Captain E. M. Pennefather has been transferred from Buttevant to Fermoy for duty at the Military Hospital. Captain B. H. V. Dunbar, from Belfast, has taken up duty at Enniskillen. Captain J. D. Richmond, from Piershill, has been appointed to Inverness. Captain C. Bramhall, from Woolwich, has taken up duty at Birmingham as Adjutant of the Royal Army Medical Corps School of Instruction to the Wessex Division, in succession to Captain F. A. Stephens, whose tenure of the appointment has expired. Captain J. A. W. Webster has been transferred from Fermoy to the Military Hospital at Cork. Lieutenant R. H. Nolan has been granted eight months' leave of absence home from India on the recommendation of a medical board.

Lieutenant H. F. Joynt, from Hounslow, has embarked for a tour of service in South Africa. Lieutenant W. P. MacArthur has joined for duty at Mauritius. Lieutenant A. S. Cane has been appointed to the Medical Charge of Troops at St. John's Wood.

INDIAN MEDICAL SERVICE.

Colonel J. Smyth has been selected for appointment as Principal Medical Officer of the Secunderabad Brigade. Colonel D. ffrench-Mullen, on the termination of his appointment as deputy to the Principal Medical Officer, His Majesty's Forces in India, has taken up duty as Principal Medical Officer of the Sirhind and Jullunder Brigades. Lieutenant-Colonel R. Bird, C.I.E., professor of surgery at the Medical College, Calcutta, and surgeon to the College Hospital, has joined the suite of His Majesty the King-Emperor during his stay in India as Extra Surgeon. Lieutenant-Colonel J. Crimmin, V.C., C.I.E., has been appointed Presidency Surgeon of the Third District, Bombay. Major F. S. C. Thompson, superintendent of the Central Jail at Alipore, has been granted one month's leave of absence. Major H. J. Walton, civil surgeon at Baharanpur, has been appointed an Ordinary Fellow of the University of Allahabad. Major E. L. Ward, superintendent of the Central Jail at Lahore, has been appointed to officiate as Civil Surgeon at Lahore during the absence on deputation of Lieutenant-Colonel W. Ronaldson Clarke. Major A. M. Fleming, civil surgeon of Raipur, has been granted leave of absence home from India for one year on the recommendation of a medical board. Major E. F. G. Tucker has been appointed to officiate as Presidency Surgeon of the Second District, Bombay, as well as Marine Surgeon and Superintendent of the Lunatic Asylum at Colaba. Major G. E. Stewart, superintendent of Mahableshwar Sanatorium, Satara District, has been appointed a Magistrate for the district under the Code of Criminal Procedure. Major R. K. Mitter has been granted three months' privilege leave of absence.

Major J. L. Majoribanks has been selected for appointment as Deputy Sanitary Commissioner of the Western Registration District, Bombay. Captain M. F. Reaney, at present employed on special duty at Pachmarhi, has been appointed Civil Surgeon to the Wardha District. Captain R. McCarrison, agency surgeon at Gilgit, has been granted one year and three months' leave of absence home from India. Captain W. M. Houston, on return from leave, has been appointed Assistant to the Civil Surgeon at Poona. Captain W. E. Brierley has been appointed Specialist in Advanced Operative Surgery to the Seventh (Meerut) Division. Captain D. Munro, Bengal Presidency, has been permitted by the Right Honourable the Secretary of State for India to extend his leave of absence home by three months. Lieutenant R. B. Lloyd, medical officer in charge of the 31st Lancers, has been granted six months' leave of absence home from India on the recommendation of a medical board. Lieutenants F. W. Hay, S. M. Hepworth, and C. A. Wood, on arrival at Bombay by the transport s.s. *Dongola*, have been posted to Bangalore Cantonment to undergo a course of instruction in Indian sanitation; Lieutenant K. G. Pandalai will be similarly posted on arrival.

THE NAVAL MEDICAL DINNER.

The Naval Medical dinner was held at the Criterion Restaurant on Dec. 19th, 1911, Surgeon-General Christopher Pearson presiding. There were present Sir James Porter (Director-General of the Medical Department of the Navy), Sir W. Watson Cheyne, Sir Dyce Duckworth, Professor W. J. R. Simpson, C.M.G. (members of the Naval Medical Consultative Board), and more than 50 medical officers on the active and retired lists. At a meeting held before the dinner it was decided to make the dinner an annual event and to form a committee to carry out the arrangements.

DEATHS IN THE SERVICES.

Surgeon Gordon Moir, R.N., suddenly, at Plymouth, on Dec. 26th last, in his thirty-sixth year, from syncope, following pleurisy and pneumonia. The deceased officer received his medical education at Guy's Hospital, London, and shortly after qualifying in 1903 was appointed house surgeon at the Hertford General Infirmary, and the year following he entered the Naval Medical Service. He served on the *Nightingale*, which was engaged on river service in China. He was surgeon to the Devonport dockyard for two years, and in October, 1911, he went to the Royal Navy College, Greenwich. He was to have joined the *Vivid* at Devonport on Jan. 1st. He was very popular in the "Three Towns."

MEDICAL MEN AND MUNICIPAL HONOURS.—Since publishing our article under this heading (*vide* THE LANCET, Vol. II., 1911, p. 1722), it has been brought to our notice that we had omitted to mention that Mr. Lee Fyson Cogan, L.R.C.P. Edin., M.R.C.S. Eng., who for 26 years acted as medical officer of health of Northampton, is now the mayor of that borough. Mr. Cogan's honour is a well-merited one because to him Northampton owes in a large measure its improved sanitary conditions. He received his medical education at Guy's Hospital and at Bristol, and after qualification in 1870 obtained a residential appointment at the Northampton General Hospital. After relinquishing this appointment he acted in partnership for five years and subsequently entered upon a practice on his own account. During his tenure of office as medical officer of the borough, in spite of considerable opposition, he inaugurated many improvements, which resulted in a great reduction of the death-rate. He did much good work in bringing about the demolition of insanitary houses and in sweeping away slum districts. Under his *régime* the voluntary notification of consumption was adopted and measures were taken to check the ravages of the disease. After resigning the medical officership Mr. Cogan was elected on the council in 1904, again in 1907, and in 1910. He takes an active part in all that concerns the well-being of the borough and holds many important public and semi-public positions. He has been medical officer for the prison since 1882, is a Fellow of the Society of Medical Officers of Health, and surgeon to the Royal Victoria Dispensary, Northampton.

Correspondence.

"Audi alteram partem."

THE MEDICAL PROFESSION AND THE NATIONAL INSURANCE ACT.

To the Editor of THE LANCET.

SIR,—The opening of a new year is a particularly convenient opportunity of reviewing our positions, of altering where necessary our plans, and of freeing ourselves from embarrassing entanglements. We shall all be glad to leave behind us the misunderstandings, the misrepresentations, and the failures of 1911. We have had our fill of criticism of the conduct of those who have been engaged for months past in framing and amending the Insurance Bill, and the time has surely come when we should turn aside from this easy and profitless task and devote ourselves to the harder task of constructive work.

The Insurance Act is now the law of the land and will become operative in a few months, and unless the medical profession is to be hopelessly belated it must at once come into line and decide how it will deal with the new social condition this Act will inaugurate. I am particularly anxious to say nothing that can be divisive or stimulating to those political passions that slumber in the breasts of all of us, and I shall not transgress if I say that we have to accept as a fact a compulsory and contributory scheme of national insurance for the wage-earning portion of our population, involving the provision of "medical benefit" for the insured. I submit that the inauguration of this scheme offers the medical profession a chance of regularising its services to the industrial classes such as may never again be presented to it, and the most urgent need just now is that we should all realise this fact and brace ourselves to the task that is presented to us. I need do no more than repeat such familiar expressions as "The Battle of the Clubs," "Club Tyranny," and "Hospital Abuse" to convince your readers that the problem of giving "medical benefit" to the wage-earning class has not up to the present been satisfactorily solved. Now is our chance of solving it. Whether we will it or not the old order is to be changed, and it will be our fault if the change is not for the better both for our patients and for ourselves.

We must not be misled into thinking—as some of your correspondents appear to believe—that the Insurance Act definitely formulates the kind of "medical benefit" that the insured are to receive. The Act is wide and vague, and until regulations have been drafted and approved definite detail will be wanting. Herein lies our opportunity. It is for us to secure that these regulations shall express the mind of those among us who are best qualified to determine how "medical benefit" can at the same time be the best attainable for the insured and consistent with the dignity and honourable remuneration of the profession.

The British Medical Association should take a chief part in evolving the needed new system, but it must not be obsessed by its "six cardinal points," or imagine that to secure those is all that is necessary. I have hoped that the Fellows of the Royal College of Physicians and the Council of the Royal College of Surgeons would also aid in the solution of the problem. Certain is it that those who are connected with the hospitals of the country will have to lend their aid. For it is clear that the "medical benefit" that has to be organised must include not only that rendered by private practitioners, but also that supplied by the cottage hospitals and by all our larger general and special hospitals.

More than once you have allowed me to express the hope that the system of "contract practice" would not be rendered universal and inevitable by the regulations under the Insurance Act. I know there is some difference of opinion as to the merits or otherwise of "contract practice," although nothing that I have heard or read on this subject has materially lessened my objection to it. But even the entire abolition of "contract practice" would not solve the whole problem of "medical benefit": that is something far wider and more complex. This "benefit" has to be rendered by every branch and order of the profession, and its organisation

and correlation demands the best thought of the whole profession.

But, Sir, I must not occupy more of your space to enlarge upon this, and I will close this letter, already too long, by indicating what, in my opinion, should be done.

I think the profession should at once free its mind from prejudice and suspicion, and, accepting merely the bare fact that the State has called upon it to render "medical benefit" to the wage-earners of the community, should form itself into a committee or committees to formulate the scheme, which, in the opinion of the profession, will give the most efficient "medical benefit," and under conditions consistent with the honour and dignity of a scientific profession. Such a scheme must include in its purview the prevention of disease as well as its mitigation and cure, it must recognise and provide for the increasingly scientific character of "medical benefit," and it must correlate all the varied agencies for affording "medical benefit," not forgetting the offices of trained nurses. When the medical experts have decided how and under what conditions the medical profession can best aid the sick workman the plan should be presented to the Insurance Commissioners and the Local Health Committees. The question for us now to answer is, Shall the scheme of "medical benefit" be formulated by these bodies and pressed on the profession or shall it be formulated by the profession and pressed upon these bodies? I urge the latter course.—I am, Sir, yours faithfully,

Jan. 2nd, 1912. ALFRED PEARCE GOULD.

To the Editor of THE LANCET.

SIR,—A second call is being made upon us. I have sent more, but also a letter expressing the hope that the British Medical Association will stiffen itself. Is it not apparent that there is really a cleavage in the profession? The upper ranks would profit by the extension of contract work and the resultant degradation of the general practitioner. I have talked to various consultants who wonder at our attitude. "Would you not like to be an officer of the Medical State service?" is the pet question. I do not believe there are enough medical men in England to work the Insurance Act. Does everyone realise that on the removal of fee visits country practitioners would be obliged to curtail their radius? What, then, would become of inter-areas which medical men could not work? Under the check of fees for visits people will walk miles in the country to save a visiting fee, and will attend at the surgery. Surgeons will have to be appointed in each rural parish, and days of attendance at stations fixed. Elderly practitioners will have to give up. There will be no possibility of cultivating private practice. The country doctor's lot will be more unenviable even than that of the rural policeman.

There is not half enough money to be earned in a workable area by a medical man in the country, and if there were enough people no one man could do the work. The public would soon find such medical attendances very inferior to what they have hitherto had. Whatever town practitioners may do, the Act is unworkable in the country. Only fair visiting fees will keep down frivolous visiting demands. In my opinion, the direct question should be asked every general practitioner, "Are you prepared to boycott the whole affair and let things remain as at present instead of taking a perilous gambler's risk, in which loss would be fatal and thousands of old practitioners would be swept away before things could be rectified?" "Slum" practices alone may benefit from the Bill; every decent practice will be seriously injured.

Another grave matter, not till now mentioned, is the arbitrary and excessive powers of Insurance Commissioners to remove a doctor's name from the panel. With the wholesale visits we should all be let in for, numerous cases of "proved neglect" would occur and the removal of the doctor's name would precede advertisement for his successor, which in a rural district would mean ruin for many a medical man. Lord Haldane asserts that the Bill would not increase illness. No, but it would vastly increase visits from the removal of the fee visit check. This little point shows how utterly superficial is the knowledge of the Government on this serious matter when they cannot see that the medical visits will be enormously increased once remove the fee check. In any case the Commissioners' powers are too great for us to submit to. When we know exactly the numbers and social position of insurable persons then only can we construct own terms (unitedly) but fee visits must never be given up.—I am, Sir, yours faithfully,

L. L THAIN, M.R.C S. Eng.

Ewyas Harold, Hereford, Dec. 28th, 1911.

To the Editor of THE LANCET.

SIR,—Allow me to point out an argument in favour of payment by work done and against the capitation fee as contemplated by the Insurance Act. Most of the domestic servants would be sent home during an illness, and in many cases their homes are at a great distance from their employers, or quite in another part of the country. In such cases a servant would naturally enter under a doctor where she works, and he would get the capitation fee; but when she is at home the country doctor cannot attend her for nothing, nor can the Government pay twice over for the same patient. On the principle of payment according to work done there will be no difficulty in paying both doctors according to the amount of their work. This argument applies also to journeymen labourers and others who often work at a different part of the country from their own homes. I am, Sir, yours faithfully,

Cambridge, Dec. 26th, 1911. U. K. DUTT.

To the Editor of THE LANCET.

SIR,—The outlook of the profession is bad because it wishes to negotiate terms of service without resort to the arbitrament of war. At present the nostrums on which we rely are: (1) pledges, and (2) guarantees. Both will do for spectacular but not for war purposes. A man's first duty is to his family and himself, and not to the profession that has undercut him and left him with a past of ineradicable scars. So much for the pledges. As to the guarantees, what business man would give the profession 15 per cent. of their face value for them? It is clear we must place no reliance on these weapons of tissue paper. Our powers of offence and defence must be independent of blacklegs, &c. If we are sure this cheap service is dangerous to the community it is our express duty to wreck it and demand a new service at the hands of the profession and the legislature. If the Chancellor does not see his way to pay due regard to our opinions and intentions and tries to force upon us the present measure we must, at the time we are called upon to carry out his plans, call out the honorary medical officers of all voluntary institutions—also all students—and at the same time call on general practitioners to boycott the panel. The question also here arises as to the expediency of calling upon wholesale chemists to support the legitimate claims of the profession. There still remains two important considerations. The doctors if defeated may treat patients, but they will be under no obligations to prevent malingering nor the prescription of good drugs if expensive. Those under the whip should retaliate according to their power. In war like this sentiment has no place until the battle is over. War is war, and our weapons must be dictated, not by choice, but by necessity.

> For when things border on impossibility
> Fine scruples have no place in men's alternatives.

The Chancellor must not be looked upon in any other light than as a man contending for a high ideal, but who is the custodian of the public purse.

I am, Sir, yours faithfully,

CHARLES WRAY, F.R.C.S. Eng.

Members' Mansions, Westminster, Dec. 29th, 1911.

To the Editor of THE LANCET.

SIR,—The following extract from "Notes for a Law Lecture," by Abraham Lincoln, July 1st, 1850, is, I think, interesting at the present moment in connexion with the question of contract medical practice:—

> The matter of fees is important, far beyond the mere question of bread and butter involved. Properly attended to fuller justice is done to both lawyer and client. An exorbitant fee should never be claimed. As a general rule never take your whole fee in advance nor any more than a small retainer. When fully paid beforehand you are more than a common mortal if you can feel the same interest in the case, as if something was still in prospect for you as well as for your client. And when you lack interest in the case the job will very likely lack skill and diligence in the performance. Settle the amount of fee and take a note

in advance. Then you will feel that you are working for something and you are sure to do your work faithfully and well.

I am, Sir, yours faithfully,
T. CUMING ASKIN, M.D. Dub.

Alderton, Woodbridge, Suffolk, Dec. 28th, 1911.

To the Editor of THE LANCET.

SIR,—As this Act enacts that Local Insurance Committees shall recognise medical committees and consult them on questions affecting "medical benefits" and the giving of treatment to insured persons, it will give the best constructive results if doctors at once form local medical committees to decide what terms they will accept when the Local Insurance Committees ask them. To aid this action I have drafted some suggestions *re* the terms to be accepted by doctors. I shall be glad to send a few copies to any person asking me for them, on receipt of 1*s.* to cover cost of printing and postage. Doctors must act at once, as the Local Insurance Committees must take action within six months.

R. R. RENTOUL, M.D.

78, Hartington-road, Liverpool, Dec. 30th, 1911.

To the Editor of THE LANCET.

SIR,—A correspondent in your last issue asks questions as to the attitude of "consultants" towards members of the profession who may be willing to work under the Act.

May I ask what is likely to be their attitude in the matter of hospital service under this same Act? They for the most part fill the positions of honorary physicians and surgeons in our voluntary hospitals, and as such will be called upon to work the Act in so far as it affects, or will affect, hospitals and dispensaries. The patients of such institutions are for the most part of the class to come under the provisions of the Act, and I think it may be said the Act contemplates the coöperation of hospitals and dispensaries for its purposes while failing to make provision for their maintenance, leaving it for the charitable to provide the bulk of the funds as heretofore. Still it does give power to approved societies or insurance committees to make subscriptions or donations, but we may be quite sure these will not be made *ad misericordiam* but for benefit to be received—a business arrangement purely. Should not the staffs of our hospitals make it clear to the management, and also to those responsible for the carrying out the provisions of this Act, that they, too, will absolutely refuse to serve? Indeed, are not those numbered among the protestants, as such, committed to such a course? Under no circumstances should they longer continue to serve under the provisions of this Act except as salaried officials of the hospitals.

I am, Sir, yours faithfully,
PROTESTANT.

Dec. 25th, 1911.

THE MORBID DIATHESES.

To the Editor of THE LANCET.

SIR,—The views of Mr. R. Clement Lucas expressed in his recent Bradshaw lecture at the Royal College of Surgeons of England respecting the medical diatheses are rather startling.[1] I have, however, reason to believe that they represent opinions which, if not generally avowed or expressed by the younger pathologists and surgeons, appear to be seriously held by not a few of them.

The line of argument adopted is that certain habits of body which have long been, and still are, recognised as specific and peculiar in respect of their intimate textural proclivities, and their reaction to disease, have no existence, and constitute but "fond imaginations" in the minds of the older physicians. These alleged constitutional habits are gradually being shown to depend exclusively upon specific microbic intrusions, and may therefore be dismissed from further consideration in the field of practical medicine. In short, the unit of pathogeny is henceforth to be completely expressed by a microbe. The soil, or textures, into which these vicious intruders penetrate and generate their toxins is to be regarded as quite immaterial; the *seed* alone is of any importance in the case. Human beings are all alike in tissue-tendency, albeit some are stronger and some are weaker, with similar constitutional reaction to all irritants and toxins, and with no special proclivities either to encourage or destroy any one of these. The older physicians are to be regarded as rather unwise men with feeble powers of observation. To-day we are living in the full light of noon, and are prepared to give rational explanations of almost all maladies and their progress, save a few for which as yet the specific microbes have eluded discovery.

Such views may possibly commend themselves to the minds of some modern surgeons and bacteriologists, but they do not happen to be in accord with careful observation and research in clinical medicine. Physicians, at all events, know full well that they have to deal with varieties of *soil* as well as of *seed*, and must regard both factors as of equal importance. Bacteriology, indeed, has abundantly tended to confirm the certainty of some of the diatheses described by our forefathers, and the old doctrine of the diatheses will never, as I venture to believe, be swept out of the field of scientific and practical medicine by any opinions or efforts of surgeons or bacteriologists.

I am, Sir, yours faithfully,
DYCE DUCKWORTH, M.D.

Dec. 27th, 1911.

[1] THE LANCET, Dec. 23rd, 1911, p. 1755.

THE DIAGNOSIS AND TREATMENT OF URINARY TUBERCULOSIS.

To the Editor of THE LANCET.

SIR,—Dr. Newman's criticism of my remarks on nephrectomy in urinary tuberculosis in his letter in THE LANCET of Dec. 16th, 1911 (p. 1735), suggests a greater difference of opinion between us than really exists. The physician and the surgeon necessarily look at the question from a somewhat different point of view. Even the material upon which their opinions are based is likely to be different, for there will be a natural selection of cases made, by which the operable cases will go to the surgeon and the inoperable to the physician. The truth will lie midway, and will be reached by a combination of the two experiences.

It is evident that on the main points both are generally agreed: 1. That in advanced cases, where the disease is bilateral or the bladder involved, nephrectomy is out of the question. 2. That where the disease is unilateral and the bladder not affected, operation is desirable and that with as little delay as possible. The only question, then, is as to the ease and certainty with which unilateral renal tuberculosis can be diagnosed in its early stages, or, in other words, the other kidney be regarded as sound.

The early diagnosis of renal tuberculosis is not so very difficult in the present day if full advantage be taken of all the recent improvements in method. But there remains the question whether the disease is limited to one kidney, and the answer given to it is of the greatest importance, for it determines the advisability or not of the operation. Post-mortem evidence shows that both kidneys are affected in not less than 30 per cent., and that even in quite early cases the affection is not infrequently bilateral. It also shows that the disease may exist in the opposite kidney in so early a stage that it could not give any direct evidence of its presence.

Another set of statistics is furnished by the results of operation, in which the number of cases cured is recorded. Unfortunately this line of inquiry often proves unsatisfactory, because while most of the successful cases are recorded the unsuccessful ones are not. The figures do not sufficiently distinguish between the immediate and remote results of operation. The mortality of the operation has nothing to do with the problem. It is no doubt small. The question is not whether the patient died or recovered from the operation but what the ultimate result was, and whether the patient was cured of the disease. Walker's statistics as quoted by Dr. Newman are not clear, but it may be noted that out of the 210 cases only 20 are described as "cures." I do not wish, however, to labour this point. There are, no doubt, some cases, more it may be hoped than we think, in which the operation has been completely successful and the patient has remained healthy for years. No doubt with improved methods his percentage of such cases will increase.

But after all we come back to the degree of difficulty in being certain in any given case that the one kidney is sound. Those most skilful in diagnosis will make fewest mistakes, but I suppose that not even the most skilful and experienced would deny that there is a fair chance of error, and therefore risk; in less skilful and experienced the greater the

chance of error. The very ease of operation increases the temptation to the surgeon. Considering that nephrectomy reduces at one stroke the renal capacity of the body by one half, the caution I expressed is fully justified, and the conclusion warranted that nephrectomy is an operation which should only be undertaken after very serious consideration and with full understanding of the risks it involves.

I am, Sir, yours faithfully,

Wimpole-street, London, W., Dec. 29th, 1911. SAMUEL WEST.

To the Editor of THE LANCET.

SIR,—I am very pleased to see that in the issue of THE LANCET for Dec. 16th, 1911, Dr. David Newman has supported the surgical treatment of renal tuberculosis in reply to Dr. Samuel West's address to the Harveian Society. In the discussion which followed this address Mr. Hurry Fenwick and Mr. Thomson Walker brought forward the surgical aspect of the treatment of this condition, and I would add my own experience on this subject.

There is little doubt that the more recent methods of clinical observation have proved that renal tuberculosis is at first a unilateral disease, and is not so frequently bilateral as was concluded from the post-mortem evidence obtained from later stages of the disease. Further than this, it has been shown that in tuberculosis of the urinary apparatus the primary focus of the disease is in one or other kidney in the great majority of cases, whereas only a small percentage commence primarily in the bladder. Walker states (*Annals of Surgery*, 1907) that in a series of 279 cases of genito-urinary tuberculosis the kidney was first involved in 184 and the epididymis in 80.

In a recent article on "Primary Unilateral Renal Tuberculosis" in the *Guy's Hospital Reports*, Vol. LXIV., I have collected 92 cases of this disease, and in an appendix to the report have tabulated 13 cases which have been under my personal observation; to these I can now add two more recent cases, making 15 in all under my own care. Dr. Samuel West terminates his address with the remarks:—

> All that I wish now to do is to protest against regarding the removal of a tuberculous kidney as an operation to be lightly decided on. It is a very grave act, requiring the most serious consideration and in all cases involving grave risks. ..... The question is not whether the operation can be safely and successfully done, but what will be the condition of the patient afterwards and how far his chance of life will be altered for better or worse.

It is in reply to this question that I wish to place before the readers of THE LANCET the results obtained in these 15 cases under my own care. No surgeon with a knowledge of renal surgery would in the present day embark upon such an operation as nephrectomy without giving "serious consideration" in each individual case, without a complete examination of the functional activity and of the freedom from disease of the other kidney. Watson has shown that operative mortality of nephrectomy has fallen from 35 per cent. to 7·8 per cent. since these examinations have been conducted.

Of the 15 cases under my care, one refused operation, although seen in an early stage, and in spite of vaccine treatment gradually became worse, and died some two and a half years after. In the remaining 14 cases nephrectomy and complete ureterectomy was performed at one operation in 13 cases, and nephrotomy and erasion of a small focus in one. Of the 14 cases, one died as the result of the operation from suppression of urine and one has been lost sight of, having gone abroad some eight months after the operation. Two cases have only been operated upon during the last 15 months, and although both are doing exceedingly well since the operation, I exclude them, as sufficient time has not elapsed to speak of the result. Of the remaining 10 cases who have survived the operation for varying periods from two and a half to six and a half years, six cases can be stated to be definitely cured, whilst four are very greatly improved, although still troubled with slightly increased frequency of micturition. I hope that these figures, even though few in number, may help to convey a different impression than that left by Dr. West's address.

I feel strongly that the correct treatment for unilateral renal tuberculosis is nephrectomy combined with complete ureterectomy, and would mention the operation I have described in the *Guy's Hospital Reports* of a separate lumbar and ilio-inguinal incision, by which means a complete bridge of abdominal parietes remains between the two incisions to strengthen the resulting scar, and by which practically the whole length of the ureter can be removed intact with the kidney and renal pelvis by an extra-peritoneal operation. That vesical infection with tuberculosis is, unless very extensive, no contra-indication to the operation of nephrectomy I am certain, for I have seen not only very marked improvement in the general health and in the vesical symptoms in these cases after nephrectomy and ureterectomy, but I have cystoscopic evidence of the complete cicatrisation of tuberculous vesical lesions after the removal of the primarily affected kidney and the subsequent treatment with tuberculin.

Apologising for the length of this letter and the encroachment upon your valuable space,

I am, Sir, yours faithfully,

Wimpole-street, W., Dec. 30th, 1911. R. H. JOCELYN SWAN.

"UNICELLULA CANCRI."

To the Editor of THE LANCET.

SIR,—Sir Henry Butlin's lectures on the above subject, and the correspondence in your columns, have brought out very clearly a fundamental fact with regard to the cancer problem, and the mental attitude of the profession towards it. The profession has set out to define "the disease cancer" in particular, without first defining the meaning of "the disease" in general. Our science is at present sharply divided into two portions; in one "diseases" are scientifically defined, in the other they are undefined. I propose to show that "the disease cancer" lies at present in the latter category. Our defined diseases consist of four main groups. We all recognise "the diseases" of parasitism, of poisoning, of traumatism, and of incomplete development. Every one of these true diseases is "a mental conception, drawn from the observation of a series of symptom-groups of determinate and similar causation." For instance, in order to define "the disease typhoid fever" a series of cases has been observed, in all of which a certain microbe is parasitic, and in which a widely varying but characteristic symptom-group occurs. By thus correlating cause and effect in a sufficient number of cases we are enabled to derive a definite and reliable mental conception, to record a true disease. But it must be observed that the "cause" is the parasitism of the typhoid microbe, and this only. All antecedent conditions, leading to each individual attack, are absolutely excluded from our definition. The days of "predisposing and exciting causes" are over. Thus, when we speak nowadays of any true disease, such as typhoid fever, we imply distinctly that we possess definite knowledge of "the cause." A moment's reflection will convince any one that this does not apply to "the disease cancer." We speak, as a matter of fact, of "seeking the cause of this disease," whereas the definition of all true diseases rests on the antecedent correlation of cause and effect in a long series of cases.

The explanation of this extraordinary situation is not far to seek. It has been the custom in our profession from the earliest times to call every recurrent recognisable symptom-group "a disease," quite irrespective of the correlation of cause and effect. So that it is probably within the mark to say that for every true disease that is recorded in medical science there are to-day twenty spurious diseases. Bright's disease, Hodgkin's disease, Addison's disease, Graves's disease, diabetes, angina pectoris, myxœdema, pernicious anæmia, gout, asthma, insular sclerosis—these will serve as examples of recurrent symptom-groups from which we derive conceptions that are called, to our confusion, "diseases"; to our confusion, because they do not represent correlated cause and effect. No one will deny that "the disease cancer' belongs at present to the latter category; it does not coincide with the true diseases; it has not been proved to be due to parasitism, poisoning, traumatism, or incomplete development. The profession is halting between two opinions; either we do or we do not know what we mean by "a disease"; can we draw a distinction, for instance, between lead poisoning and Hodgkin's disease, or can we not? I say we can; because our conception of lead poisoning is founded on correlated cause and effect, while our conception of Hodgkin's disease obviously is not. If this be true, then cancer is merely a recurrent, recognisable symptom-group, of which the cause is still unknown. Modern research seems to me to have placed it almost

beyond doubt that the symptom-group called cancer is always due to one and the same cause; and that it is not due to parasitism, poisoning, or traumatism; in other words, that it is not due to a cause of extrinsic origin, to any interference from the environment. The manner of growth that characterises the cancerous tumour is, to my mind, to be accounted for only by some disturbance or dislocation, temporary or permanent, of the normal processes of growth; there is, as the older physician would have said, some constitutional flaw at work. The hopeful aspect of the situation lies in the fact that we already know a great deal concerning the antecedent conditions that lead to this constitutional dislocation in individual cases. It is enough to mention sweep's cancer, but of the "cause" we have as yet no positive knowledge. This ignoring of the constitution, of the intrinsic causes of disease, is not confined to the case of cancer; it has been a feature of modern medicine ever since "pathology" and its "organic diseases" took possession of our science. The search of our scientists is now for "the anatomical seat of the disease," to quote from the official "Nomenclature of Diseases," a phrase to which I defy anyone to attach a rational, not to mention a scientific, meaning.

In many cases of diabetes, asthma, epilepsy, insanity, hysteria, it is obvious to all that the cause of the symptoms shown does not arise in the environment of the patient; it must therefore arise in his constitution, it must be intrinsic in origin. Instead of recognising this fact, the cause is simply ignored in the definition of all such "diseases"; we call recurrent symptom-groups by the same name as our true diseases, with the result that one-half of our science is left unsystematised. An exception is made in the case of one group of diseases of intrinsic causation; incomplete development is recognised as a cause of disease on a par with parasitism, poisoning, and traumatism. The diseases of incomplete development are true diseases, because on the basis of correlated cause and effect we frame definite conceptions of them; how long will it be before the other intrinsic causes are recognised? If cancerous symptoms prove, as I believe they will, to be of intrinsic causation, it will not be possible to differentiate "the disease cancer" sharply from other conceptions, as typhoid fever is differentiated; it will merge insensibly into other diseases, such as keloid. There are always indefinite and arbitrary lines, and borderland cases, amongst constitutional diseases.

My case may be summarised by saying that three conditions, not one of which is at present recognised, must be complied with before the solution of the cancer problem can be reached; the definition of "a disease" as "a mental conception, drawn from the observation of a series of symptom-groups of determinate and similar causation," must be accepted as a definite and universal standard in medical science; the intrinsic causes of disease must be recognised as being on an equality, scientifically speaking, with the extrinsic causes. It is also essential that antecedent conditions—which belong to the individual, actual attack, and are variable—be clearly differentiated from the "cause," which is constant, and on the correlation of which with a recurrent recognisable symptom-group depends the recognition, the definition of every true disease. At its present stage the solution of the cancer problem demands, above all things, broad and clear thinking.

I am, Sir, yours faithfully,

Clevedon, Dec. 17th, 1911. SYDNEY W. MACILWAINE.

To the Editor of THE LANCET.

SIR,—Sir Henry Butlin—I think truly—says "students of cancer, research workers, biologists who have studied cancer, are all practically agreed that the cancer cell is derived from the cells of the part in which it takes its origin." At the same time I think the majority of scientists who are not in the above category feel that the parasitic theory of cancer falls more into line with the broader principles of medical knowledge. Personally I feel that the latter view is more likely to be correct, and welcomed Sir Henry Butlin's paper as supporting it. But after coming to the conclusion that the unicellula cancri is "an independent creature," it is a little surprising to find that he is obliged to bring in heterogenesis as the explanation of this. Surely one must make very certain that there is no other explanation possible before adopting a theory which is now almost universally discarded.

The ground on which he bases his belief that the cancer cell is formed within the body is the close resemblance of its appearance and reactions to those of the cells around. Cannot this, however, be explained as being an analogy in parasitology to what occurs in zoology in the case of protective adaptation to environment? In other words, may it not be that the cancer cell, by closely resembling in its reactions the normal cells around, escapes the vigilance of the phagocyte, and so is enabled to gain a footing and proliferate?

I am, Sir, yours faithfully,

Brook-street, W., Dec. 29th, 1911. J. BRUNTON BLAIKIE.

THE HEALTH SEASON IN EGYPT.

To the Editor of THE LANCET.

SIR,—Many people who are more or less invalids find it desirable to leave England during the winter months for some place where the climate is warmer and drier, and of these not a few naturally think of Egypt. I find that there is a more or less prevalent idea that there are reasons why, *this year*, Egypt should not be selected as a place of residence. So far as I can make out it is supposed that travellers run some risk: (1) from the war between Italy and Turkey; and (2) from the possibility of cholera breaking out in Egypt. As regards the war, a few minutes' consideration will convince any reasonable person that Englishmen run no risk whatever. Egypt, in spite of alarmist statements in some of the newspapers, has never been more tranquil than at present. The very slight disturbance in the lower quarters of Alexandria, which lasted for a few hours, some weeks ago, though much exaggerated in one of the London newspapers, was not to be compared for one moment with the riots which occurred in many English towns a few months ago and did not affect English residents or tourists at all. No other disturbance of any kind has occurred. The danger of any attack on life or property exists only in the minds of alarmists in England and is not seriously contemplated in Egypt.

As regards cholera, the precautions taken at the Egyptian ports are so stringent that an outbreak of cholera is practically impossible. I am pleased to find, too, from practical experience that the precautions are not confined to the ports, but that the address of every traveller who has touched at an infected port is taken and notified to the sanitary officer of the district or town he goes to. So that should a sporadic case by any chance pass the frontier it would be dealt with very quickly, and I believe effectively. Some discomfort—i.e., one or two days' detention on the steamer which has conveyed them—may be inflicted on tourists who have come from an infected port. But those coming from England by sea (not touching at an infected port) or those coming overland by Marseilles or by the excellent service *viâ* Trieste and Austrian Lloyd steamers would suffer no inconvenience whatever.

I am so convinced that residence in Egypt is as safe this year as any other year that I have brought out my wife and family, and I write these lines to do what is possible to dissipate the rumours I have alluded to.

I am, Sir, yours faithfully,

Helouan, Egypt, Dec. 11th, 1911. R. ACKERLEY.

THE EVOLUTION OF MODERN GYNÆCOLOGY.

To the Editor of THE LANCET.

SIR.—In the very interesting article on the Evolution of Modern Gynæcology, by Dr. Arthur E. Giles, in THE LANCET of Nov. 25th, 1911 (p. 1470), the honour of having performed the first complete extirpation of the uterus and ovaries by the abdominal route, and of having done the first successful hysterectomy for fibroid tumour, was given to Charles Clay of Manchester. Without desiring to minimise the remarkable achievements of Charles Clay in the early days of abdominal surgery, the above statement seems to demand some correction.

On Nov. 17th, 1843, Nov. 21st, 1843, and on Jan. 16th, 1844, Charles Clay opened the abdomen and removed fibroid tumours of the uterus. The third operation is the first recorded abdominal pan-hysterectomy. All of these operations were based upon the erroneous diagnosis of ovarian tumour, so that in no case was the operation started with

the intention of doing a hysterectomy. In 1842 Charles Clay had likewise made a similar mistake in diagnosis, but he abandoned the operation when he discovered the tumour was uterine.

The first deliberate hystero-myomectomy was that performed in June, 1846, by John Bellinger, of South Carolina, U.S.A. The patient, a coloured woman, died upon the fifth day from peritonitis. The first successful hysterectomy was performed by Walter Burnham, of Lowell, Massachusetts, on June 26th, 1853. This was not a deliberate operation, as Burnham considered the tumour to be ovarian. After the incision was made the patient vomited, forcing the uterus, the fibroid, and associated ovarian tumours out of the wound, and as Burnham was unable to replace the mass he did a supravaginal removal of the uterus, with ligation of the lateral arteries. A left ovarian tumour was removed and a right ovarian tumour also incised. The ligation of the ovarian and uterine arteries in the broad ligaments is similar to that of the modern operation. Burnham continued to do the operation from time to time, performing altogether 15 operations, but only three of his patients recovered.

The first deliberate and successful hysterectomy for fibroid tumour was performed by G. Kimball, of Lowell, Massachusetts, on Sept. 1st, 1853. Kimball had a clear concept of the diagnosis, and in his writings advocated the operation. Previous to 1856 Kimball operated four times for fibroid tumours of the uterus, with but one recovery. The successful operation of E. Koeberlé was not performed until April 20th, 1863. The first successful abdominal myomectomy is apparently that of W. L. Atlee, of Pennsylvania, performed on August 28th, 1844. This was not a deliberate myomectomy as the tumour was supposed to be ovarian, but the ovaries were found to be normal at the necropsy three years later.

The honour of having performed the first deliberate hysterectomies for fibroid tumour seems to belong to the following surgeons in the order named:—Bellinger, Kimball, Burnham, Clay, and Koeberlé. For a fuller discussion of the subject and a careful tabulated bibliography of the early operations for fibroid tumours, reference may be made to the article by Noble in the *American Journal of Obstetrics*, Vol. XL., No. 2, 1899.—I am, Sir, yours faithfully,

Philadelphia, U.S.A., Dec. 18th, 1911. W. WAYNE BABCOCK.

THE PRESCRIPTION OF TUBERCULIN.

To the Editor of THE LANCET.

SIR,—I can see nothing in Mr. Gamble's letter to modify my opinion. Whatever terms are used, and however explicit the physician may be to indicate his intentions, one comes back to the fact that he is ordering a specific fluid, and the dilution of that fluid must be calculated in measures. In my last communication I referred to Koch's bacillary emulsion, because at the time I was making dilutions of that fluid, but it applies with even greater force to Koch's new tuberculin T.R. 1 c.c. of this fluid contains the active bacterial matter of 10 milligrammes of tubercle bacilli, which represents 2 milligrammes of solid substance. I have seen the dose of T.R. indicated in decimals or fractions of a c.c. of that fluid, in fractions of a milligramme of tubercle bacilli, and in fractions of a milligramme of solid substance. Therefore it would be far better, and would avoid any possibility of confusion if it were always ordered in decimals or fractions of a c.c. of the original fluid. Personally, I prefer to work in decimals. I am, Sir, yours faithfully,

London, Dec. 19th, 1911. P. W. SQUIRE.

"GREEN" TEA.

To the Editor of THE LANCET.

SIR,—I have had a good deal to do with China tea, and therefore I am much interested in your annotation on p. 1786 of THE LANCET of Dec. 23rd. Your correspondent says that formerly Prussian blue was used for colouring the leaf in "green" tea. I should be very much obliged if you would ask him to supplement his interesting letter by stating what evidence there is of the former use of this pigment. The statement was freely made in this country some 35 or more years ago, and to it was largely due the disuse of green tea and the ruin of the trade in green tea in this country; but I do not think it was made on any sure basis of fact. For all that it may have been true, and I should be glad to know if your correspondent has any evidence to offer.

I am, Sir, yours faithfully,

Duchess-street, W., Dec. 29th, 1911. E. MUIRHEAD LITTLE.

SPONGE EDUCTION.

To the Editor of THE LANCET.

SIR,—In your issue of Nov. 11th, p. 1348, you have an annotation on "Sponge Eduction." This I read with much interest, but would point out that this is by no means a new form of treatment, and I do not think it had its origin in America, as you suggest. In 1889 Mr. A. G. Miller, surgeon to the Royal Infirmary, Edinburgh, regularly taught his students the advantages of applying prepared sponge for encouraging the growth of granulations. He termed his system "sponge grafting." His then house surgeon, Mr. Alexander Miles (now surgeon to the Royal Infirmary, Edinburgh), will doubtless recollect these successful experiments. In 1892 I was consulted by a lady with a large callous ulcer on her leg. She informed me that this had been present for over ten years and had resisted all treatment. Following the method taught by Mr. Miller, I sponge-grafted the leg, and in four months the ulcer had disappeared, leaving a firm cicatrix. I met my patient in 1908, and she informed me that the leg was in excellent condition and had given no further trouble. In numerous cases I have tried Mr. Miller's so-called "sponge grafting" to encourage growth of granulation tissue and invariably with good results.—I am, Sir, yours faithfully,

DAVID DONALD, M.D. Durh.,
L.R.C.P. & S. Edin., L.F.P.S. Glasg.

Victoria, British Columbia, Dec. 4th, 1911.

*** In this regard we may mention a letter in THE LANCET of Nov. 25th, 1911 (p. 1516), where the work of Professor D. J. Hamilton is quoted.—ED. L.

THE ACTION OF RADIUM ON MALIGNANT GROWTHS.

To the Editor of THE LANCET.

SIR,—Many explanations have been advanced as to how radium acts in cases of malignant growths. Some authorities, such as Wickham (Paris) and Finzi (London), maintain—and, I think, with good cause—that radium exercises a selective or specific action on cancer cells, while others, among whom may be mentioned Bashford (director of the Imperial Cancer Research) and Mansell Moullin, refuse to see any such selective action, and state the action of radium is merely that of a powerful caustic. Its action in such a case might be comparable to that of arsenic paste, zinc chloride, potassium bichromate, and other chemical caustics the application of which has occasionally given good results in cancerous growth.

A third theory, propounded by Deane Butcher, is that radium possibly acts as a vaccine, its rays exciting the leucocytes to the production of antibodies. In support of this it might be stated that the opsonic index has been found raised after applications both of X rays and radium.

Dominici,[1] in an interesting article, shows by means of microscropic sections the gradual retrogression of a case of sarcoma under the influence of radium. Briefly, the sarcoma is converted into a fibroma, which is eventually changed into scar tissue. The changes described are apparently of the same nature as those occurring in the "spontaneous or natural cure of cancer."[2]

Dominici, moreover, demonstrates that this fibroma is not made up of the vascular connective tissue which exists between the sarcomatous cells, but is a result of the transformation of the sarcomatous element itself. Briefly, this change, he says, is brought about in the following manner. 1. A metamorphosis of some of the protoplasma of the plasmodial elements as well as the sarcomatous cells into connective tissue fibres. 2. A transformation of the remainder of the protoplasma and of the nuclei of the sarcomatous elements into permanent fibrous tissue cells. 3. *The obliteration of the blood-vessels.* I have purposely

[1] Archives Générales de Médecine, Radium Number, July, 1909.
[2] Handley; Brit. Med. Jour., March 6th, 1909.

placed the last heading in italics, because here seems to me to be a possible explanation of the action of radium on new growths.

I have been using radium in my practice during the last two years, and the chief thing that has struck me about it is its wonderful influence on blood-vessels and lymphatics. The remarkable power that radium has in arresting hæmorrhage was referred to by several speakers at the last annual meeting of the British Medical Association. It may, in fact, be stated that its chief utility in therapeutics is its power of obliterating blood-vessels or spaces, as witness the way in which it removes various forms of nævi and angiomata. Now it seems to me that this action of radium on vascular tissues will equally explain to a large extent its beneficial influence in new growths. The obliteration of the blood channels which ramify in and supply the growth would in great measure tend to cut off its source of nutriment, which must eventually result in the death and disappearance of the growth.

I have been tempted to write the above not as anything new, the action of radium on blood-vessels being well known, but because as regards new growths this special property of radium seems either to be forgotten or kept well in the background.—I am, Sir, yours faithfully,

FERNAND L. DE VERTEUIL, M.D. Edin., M.R.C.S. Eng., L.R.C.P. Lond., Surgeon R.N. (ret.).
Vancouver, British Columbia, Dec. 17th, 1911.

MOTORING NOTES.

(FROM A SPECIAL CORRESPONDENT.)

The Advantage of Aluminium in the Construction of Pumps and Radiators.

AN unfortunate accident which took place recently through a low night temperature impels me to give this personal reminiscence, though it reflects in an adverse way on my care in automobile matters; still, my experience may be of service to others. My car is housed in an unheated shed, and to obviate the trouble of emptying and refilling the water-tank I have always added some 20 per cent. to 25 per cent. of glycerine—that is, 60 to 70 oz. of glycerine in each gallon of water used. When a recent seasonable temperature set in, I had only a winchester of glycerine in the house. This worked out at 36 oz. to the gallon, which I thought enough for one night's safety. That night the thermometer fell to 17° F., and, on inspecting the car on the following day, the pump was found to be frozen. With great care and gradual warm fomentations a thaw was effected, but a crack resulted in the water-pump casing. As chance had it, the casing was of aluminium instead of the more usual gun-metal. In this instance the lighter and softer substance proved an advantage. Without removing the pump the crack was thoroughly stopped by gently tapping with the end of a small hammer along the fissure. I think this shows the advantage of aluminium for radiators and pumps, for if a split occurs the careful use of a hammer will effect a cure. The moral, of course, is that when adding glycerine 70 oz. should be used for each gallon of water.

The Danger of a Flooding Carburetter.

I recently heard of a friend's car—it was an old 6 h.p. Wolseley—which, after a strenuous life of some eight years, finished its career by catching fire near Ladywell Bridge. An inquest revealed that as a result of wear, brought about by constant jarring, the needle-spindle of the carburetter just above the cone had worn, resulting in the formation of a slight exostosis or shoulder. This occasionally fouled and prevented the valve closing. The carburetter then flooded, the overflow pipe thus exuding petrol, and the mixture becoming too rich. In the case under consideration the exhaust pipe had become red hot and set fire to the escaping petrol. A little emery paper and elbow-grease on the carburetter valve-stem would have prevented this sad end of a noisy but capable and hard-working little runabout.

A Useful Petrol Filter.

Messrs. Brown Brothers, Limited, have placed on the market a filter which certainly separates every particle of foreign matter and water from the petrol. The petrol enters through a pipe from the upper part of the filter, and the pipe projects low down into the body of the filter. If there is any water or grit, this sinks to the bottom, whereas the petrol itself, being lighter, is forced up through a conical-shaped gauze strainer to the outlet, and thus to the carburetter. Beneath the filter a cock is fitted for draining off the impurities. Probably the commonest cause nowadays of a roadside stop is a choked jet, so this little accessory is worth considering by the owners of all cars on which a petrol-straining device is not fitted.

Regarding the Use of the Brakes.

When recently chatting with a repairer he was somewhat sarcastic regarding the lack of sympathy which many of his doctor clients had for the braking mechanism of their cars. The side brakes should be the chief ones to employ, as they do not cause any strain on the transmission. The trouble with most modern cars is that the side-brake lever is usually outside the body on most of the torpedo variety, and therefore rather difficult to reach, especially when the hood is up, thus fostering the bad habit of so many motorists, who chiefly depend upon their foot brake. The remedy would be for manufacturers to make the foot brake act on the wheels, and the hand one on the cardan shaft. This is done on one or two cars, and might be introduced with advantage on others. The engine itself is an excellent brake, and if the second, or on very steep hills the first, speed is slipped in, and the ignition turned off, most hills can be negotiated without using either brake. New shoes are, it is true, inexpensive. Still, they take a little time to fit, and by descending hills in this way the necessity for replacing these parts may be indefinitely postponed. Should the shoes wear, they can still be used if trued in the lathe and then covered with raybestos, which is composed of asbestos and brass wire and produces more friction than even metal to metal. It is supplied in varying thicknesses, so as to be adaptable to any worn drum or shoe. It should be fixed by countersunk rivets. It will also help to do away with the "chattering" that worn metal-to-metal brakes develop.

A Useful Step Mat.

At this season of the year all who desire to save the unpleasantness of having the interior of their car stained with muddy footmarks should fit some form of mat on the footboard. Fibre mats when thus exposed to wet are apt to rot, and therefore the Duco Leather Step Mat is an improvement. This is made of leather, and is impervious to petrol and grease, and is durable. It is supplied either with or without a brass bound frame, and does not in any way detract from the appearance of the car—in fact, it rather adds to it—and ensures that the interior of the car will, in spite of the mud on the road and pavement, always look clean.

Regarding Monobloc, Twin, and Single Cylinders.

A good many readers have written regarding the advantage or the reverse of the monobloc over the twin and single cylinders. Like most things in this world, each type of casting has its advantages and disadvantages. I have chatted on this subject with motor manufacturers, engineers, and founders. The general opinion seems to be that for motors of low power, such as are usually used by medical men—that is, from 12 to 18 horse power—there is much to be said in favour of the cylinders being cast *en bloc*. They permit of smaller engine length, are rigid, and though the cooling may not be as uniform, still it is enough for low powers, and the cost of construction and erection is less, and therefore the selling price is also lower. The cost for the pattern is a little more, but this is more than made up for by the reduced expense for machining. With the monobloc all four cylinders can be bored and the base planed and drilled at one operation. Of course, it means as a rule only three bearings for the crank, but the old adage, "One throw, one bearing," does not apply to low powered explosion engines, and as a matter of fact even two crank bearings have been found quite satisfactory. The only real disadvantage is that when they are dismantled for cleaning or repair, they are heavier to lift and more difficult to replace. Still, a pulley can generally be easily rigged up, and with a little care and a helper, the job can be done. On this point I speak from experience, as I have carried it out myself. A further objection is the expense of replacement, should one cylinder crack. Well, this may be dismissed, as if glycerine is added to the water in winter,

and the engine is kept oiled and cooled, it is unlikely to need replacement. If it does, it is the owner's fault for failing to safeguard against avoidable risks.

BRISTOL AND THE WESTERN COUNTIES.

(FROM OUR OWN CORRESPONDENTS.)

Lord Haldane Elected to the Chancellorship of Bristol University.

AT a meeting of the University Court on Dec. 20th the Right Hon. Lewis Fry, who presided, proposed the election of Lord Haldane to succeed the late Mr. Henry Overton Wills as Chancellor. He spoke of the strong impetus to the extension of university education which Lord Haldane had given by work and word, and referred to the great powers of organisation which he had shown at the War Office. He spoke also of the distinction he had attained as a student of philosophy, and said that there was no one who would impart greater honour to the University than Lord Haldane. The proposition, having been supported by Mr. G. A. Wills, Professor T. H. Warren (President of Magdalen College, Oxford), Sir Isambard Owen (the Vice-Chancellor of the University), and others, was carried unanimously. It is understood that Lord Haldane will address the University during 1912 if his engagements permit.

Bristol Medical Men and the Insurance Act.

On Dec. 19th over 200 members of the medical profession met in the small hall of the University under the auspices of the Bristol division of the British Medical Association to hear a report of the recent representative meeting from Dr. George Parker and to discuss the situation. All the unfortunate bitterness and useless spirit of faction which have been only too conspicuous at some such meetings in the country were happily absent. This was due in large measure to the statesmanlike speech of the chairman, Mr. H. F. Devis, who said that much as the present position was to be deplored it was unfair to throw all the blame on the Council of the Association, since they were only carrying out the policy to which they had been committed by the Association's representatives. He regarded the outlook as gloomy, the position being this: that the securing of reasonable terms under the Act depended entirely on the local strength of the profession and the pressure which could be brought to bear upon the Health Committees. Nevertheless, he felt hopeful that the federation scheme put forward by the Bristol division would be accepted by the Association and by the profession as a whole, and that if so there would be an organisation powerful enough to fight successfully all the public bodies with whom the profession would be brought into contact. The principles of the proposed federation were explained by Mr. G. Scott Williamson—viz., democratic control, financial guarantee against loss due to the action of the federation, coöperative powers, recognition of vested interests, full money-raising powers, and unrestricted control over its own funds. Each member would pay an entrance fee of £2 and an annual subscription of £1 5*s*. After signing the memorandum of federation, as each member would have to do, he would make himself thereby liable for £5 in the event of winding up, and only in that event. Resolutions urging the adoption of this scheme by the Council of the Association, authorising its advertisement throughout the profession, and resolving upon a provisional call to local practitioners, were unanimously agreed to.

The Bristol Anti-tuberculosis Dispensary.

Bristol stands committed to the support of a tuberculosis dispensary similar in most respects to those already at work in Edinburgh, Paddington, and elsewhere. A house has been taken and furnished in Redcliff-parade, close to the principal thoroughfare connecting the centre of Bristol with densely populated areas on the Somerset side of the Avon, and only five minutes' walk from Bristol Bridge. For the first year, at least, it will depend upon a large sum of money given to equip and start the work by a lady who felt that such an institution was needed in Bristol. A whole-time medical officer, with previous experience in a similar institution, has been appointed, and the work will actually begin early in the year. It is being administered in connexion with the Civic League of Personal Service, which has absorbed and replaced the Charity Organisation Society in Bristol. Bristol is to be congratulated on priority in one respect; this dispensary is the first, I believe, to make definite terms with the local profession before starting. Patients will not be received unless they come from a qualified medical practitioner. This should prove a useful precedent in the solution of the out-patient problem, which demands solution nowhere more urgently than in Bristol.

Jan. 2nd.

WALES.

(FROM OUR OWN CORRESPONDENT.)

Tuberculosis in the Rhondda Valleys.

IN a report to the Rhondda urban district council on the compulsory notification of pulmonary tuberculosis, the medical officer of health, Dr. J. D. Jenkins, expresses the opinion that if suitable measures are taken in conjunction with the notification, and if those measures are prosecuted with thoroughness, diligence, and tact, it may be possible to eradicate the disease. The average yearly death-rate from phthisis in the Rhondda during the past ten years has been 0·96 per 1000 of the population. Dr. Jenkins estimates, therefore, that there are at the present time between 400 and 500 cases in this district, which has a population of nearly 160,000 persons. He considers that the steps to be taken as the result of notification should include advice to the patient and friends by officers of the council, with general instructions for the prevention of infection; the establishment of a tuberculosis dispensary and of an observation station—these for treatment as well as for the purpose of education in the adoption of means designed to prevent the spread of the disease and to maintain and improve the patient's condition after return home; and the formation of open-air schools. The observation station recommended could most suitably be established as an annex to the council's isolation hospital, for reasons bearing upon management, administration, and facilities for treatment, and could most conveniently be run in close connexion with a tuberculosis dispensary, which would naturally form the out-patient department of the observation station.

Verminous School Children in Carmarthenshire.

It is to be regretted that in his determined efforts to improve the physical condition of the Carmarthenshire school children the school medical officer of that county, Mr. D. A. Hughes, is not receiving adequate support from the members of the local education authority. He reported some time ago to the authority that in particular schools there was present a large number of verminous children, but no action such as is possible under the Children Act was taken, so that the only course open to him was to exclude the children in question from school attendance. This action brought down the average attendance so largely that the chairman and other members of the authority raised a protest and appeared to consider that it was quite a normal condition for a child to be infested with vermin and lice. The school medical officer, said one member, had very excellent theories, but it was a question whether the country had progressed sufficiently to enable them to be put into practice. For hundreds of years the children had been taught in a dirty condition, and if they were going to take drastic measures to change the habits of the people they would only bring the authority into disfavour.

Cardiff Mental Hospital.

The latest report of the Commissioners in Lunacy on the Cardiff Mental Hospital bears testimony to the excellent research work that is being carried out in the pathological laboratories attached to the institution. Mr. R. V. Stanford, M.Sc., a few months ago was appointed research chemist to the hospital, and Dr. H. A. Schölberg, who has been acting temporarily as pathologist, has now been appointed permanently to that position. In 1910 the recovery rate of the asylum, as reckoned on the total admissions of the year, was 46·7 per cent., an increase of 11·3 per cent. on the rate of the previous year. As many as 81·5 per cent. of those who recovered were discharged within ten months of their admission.

Jan. 2nd.

SCOTLAND.

(FROM OUR OWN CORRESBONDENTS.)

Scotland and the Insurance Act.

THE attitude of Edinburgh towards the Insurance Act has been indicated in THE LANCET and in the letters communicated to the daily newspaper press by medical men, and quoted in THE LANCET. In Edinburgh, as elsewhere, there has been a difference of opinion as to the failure or not of the Council of the British Medical Association to act up to the expectations of the bulk of the members of the profession. There has also been a corresponding difference of view as to the action of the Council in regard to Mr. Smith Whitaker's appointment. To understand the attitude of Edinburgh it is necessary to know that Edinburgh and Leith form one division of the Edinburgh Branch of the British Medical Association, and that Edinburgh and Leith have a Medical Practitioners' Association which is made up mainly of men who are members of the British Medical Association. The result is thus somewhat confusing to the outsider, for the same persons may appear to-day as members of the British Medical Association Division, and to-morrow as members of the Practitioners' Association. As regards the action of the Edinburgh and Leith Division of the British Medical Association, the members passed, by a large majority, a vote of censure on the Central Council; they also, by a majority of two to one, passed a vote of boycott on the Act, meaning thereby that they disapproved of forming Local Medical Committees under the Act. When the same body met as the Practitioners' Association within a week later there was no motion of boycott proposed, the main motion then being to form a National Medical Union, presumably after the fashion of Lancashire. The newspaper writing referred to has shown the two sides or two drifts of opinion. The one side says boycott *now*—have nothing to do with the Act, and tell the Commissioners so, or tell them that if they do not incorporate the six cardinal points in their regulations the profession will not form Medical Committees or in any way recognise the existence of the Act in their medical work. The other view is that the Medical Committees ought to be formed, that they should formulate the conditions under which work under the Act can be done, and, if these cannot be granted, that the doctors in the area will decline to work under it. The persons in favour of the first of these policies are enthusiastic, and think Scotland only needs a lead to adopt their policy all over the country. They think that the Insurance Commissioners for Scotland will issue regulations to the insurance areas with regard to the terms of medical practice, and they seem to make no allowance for the possibility of the Commissioners asking the different insurance areas to send to them the proposed terms of medical service. The practical question, if the Commissioners adopted the latter method, would at once be, Are the doctors in the areas to abstain from stating their terms beyond parrot-like reiteration of the six cardinal points? A policy of boycott in the insurance areas at the moment they are asked to state their terms more definitely would not in ordinary business be regarded as reasonable; at all events, it would only be reasonable if the profession in Scotland were unanimously to decide that the Act was so bad that they now and for ever washed their hands of it absolutely and completely, and would have nothing to do with it, save to pay their share of the taxes imposed by it. The impossibility of such unanimity may be gathered from two recent meetings—one, held in Glasgow on Wednesday, Dec. 27th, where a policy of boycott at the present stage got 36 supporters, but was defeated by "an overwhelming number of votes"; the other, held in Stirling on Thursday, Dec. 28th, of the Stirling, Clackmannan, and Kinross branch of the British Medical Association with a large attendance. At this meeting the following was unanimously agreed to:—

> In order to carry on negotiations with the Scottish Insurance Commissioners immediate arrangements be made for the establishment of Local Medical Committees throughout the area of the branch, and the subsequent appointment of medical representatives on the Local Insurance Committees.

The secretary was instructed to inform the Commissioners that every medical practitioner in the three counties covered by the branch had signed an undertaking not to enter into any arrangement for the medical treatment of patients until the six cardinal principles of the policy of the Association had been embodied in the regulations of the Commissioners. The policy of national boycott, at this stage of the proceedings, would thus appear to be unattainable. The argument, which is regarded as strong in favour of immediate boycott, is that the profession will be beaten in detachments by the Commissioners. In Scotland I have no apprehension on this point. The tone of the resolution of the Stirling branch is the tone of rural and urban Scotland, and will become more and more pronounced as weeks pass. The Scot has become *dour*, and when that happens there will be no quarter given by the profession in Scotland, in any county, to the Act and its backers, or to the Commission. Whatever may be the position in England, Scotland has never dreaded the guerilla war which seems likely to be thrown upon it. Here many men seem to have readily adopted the change in strategy which became necessary, and are confident that they will either get their terms in the areas or absolutely block the Act. The guerilla war, indeed, promises to weld the rural, and probably the urban, practitioners very closely together in the different areas. The policy of boycott, as a general policy for Scotland, does not therefore appear to be hopeful, unless the Commission turns out to be more stupid or more autocratic than is probable. Many of us who think boycott at present unstatesmanlike would be much pleased if the Commission acted so as to secure such a boycott all over Scotland, and there are points regarding which Scotland will not parley. So much may be taken as fairly expressing the opinion of Scotland, although I have not attempted to conceal my own leanings and my own optimism, based on what I have seen and what I know of the temper of the Scottish doctor at the present time.

The Proposed Scottish Central Committee.

One other important development has just reached a stage at which it can be referred to publicly. It has been an open secret for some time that the three Scottish medical corporations have been considering for weeks past whether they could do anything at the present juncture to help the profession in Scotland, seeing that Scotland was to have a separate Commission to work the Act. The problem was an exceedingly delicate one, and Scotland may, I venture to say, be congratulated on the solution which has been offered. The three corporations suggest the formation of a Scottish Central Medical Committee, to consist of representatives from the three corporations, from the four Universities, of the Scottish Committee of the British Medical Association, and of a representative practically from each insurance area. The corporations also practically offer to take their full share of the expense of the scheme. A statement has been made, and a meeting of the Scottish Committee will, it is expected, be also held shortly, with a view to determine what its attitude is to be towards this scheme. Needless to say, it is hoped that the Scottish Committee will put no obstacle in the way of their cordially coöperating in it. Such a central committee can act partly as a headquarters staff and partly as a body upon whom the Local Medical Committees can fall back for support against the Local Insurance Committees or the Commission. So far as can at present be seen the areas will insist upon having local option—that is to say, that while one area may determine to refuse to have anything to do with the Act, another area will formulate the conditions on which they can work under it. The policies are not really inconsistent; the difference lies in one set of persons dreading the local conflict, while another set is resolved to insist on getting the terms suitable to their area or not working. It will be months before any further progress can be made, and meanwhile the profession will have to consider some of the problems that will soon have to be faced, and also to determine whether a canvass may not have to be made on the point of boycott at the present stage, or at the next stage—that is, through the Local Medical Committees acting in coöperation with the Central Scottish Committee. All the omens point towards the profession in Scotland giving an excellent account of themselves in the coming struggle: they are resolved to get their terms or not to work.

Edinburgh Royal Infirmary.

The report of the managers of the Edinburgh Royal Infirmary for the year 1911 has just been issued. The total

number of patients treated in the wards during the year was 12,610, as against 12,342 in 1910. The average daily number of children in the wards was 81, as against 85 in 1910. The average daily number of patients in the wards was 846, against 842 in 1910. The largest number of indoor patients on any one date was 882, and the average time each patient was under treatment was 24·9 days. Of the total 12,610 cases, 4299 were medical and 7515 surgical. There were during the year 577 deaths. Of these, 196 took place within 48 hours after the patients' admission and occurred mostly in cases of severe injury or of a hopeless nature when admitted. The percentage of deaths to cases treated was 6·9, or 5·4 if the deaths within 48 hours be excluded. The out-patients during the year numbered 38,871. The total ordinary income was £37,142 2*s*. 2*d*., an increase of £1012 18*s*. 3*d*. on that of the preceding year, and the highest ever recorded in the history of the institution. Of the total income £21,632 17*s*. 9*d*. were derived from voluntary contributions, and this source showed an increase of £520 5*s*. 9*d*. over the amount of the previous year. Advances are also shown under all the other heads of ordinary revenue, the increase in payments for hospital tickets alone amounting to £173 1*s*. The ordinary expenditure amounted to £54,851 17*s*. 2*d*., an increase of £633 11*s*. 10*d* on the expenditure of the previous year. Of this increase £307 2*s*. 11*d*. falls under the house steward's department and is mainly due to increased cost of provisions. The cost per occupied bed (including the cost of the out-patient department) was £64 16*s*. 7*d*., an increase of 8*s*. 9*d* over the cost in the previous year. Of this increase 5*s*. 7½*d*. was due to increased cost of maintenance and 5½*d*. to increase in medical expenditure. Legacies and donations of £100 and upwards to the general funds amounted to £25,265 15*s*. 6*d*. Extraordinary expenditure amounted in all to £4586 18*s*. The chief items under this head were new quarters for the nurses, extension of the nurses' dining-room, and Professor F. M. Caird's theatre. The average number of nurses and probationers on the staff during the year had been 263 5. There were 640 applications for admission to the training school during the year. Seventy-six trained nurses had left during the year. The period of training for nurses had been extended to four years. In addition to the usual courses of lectures for nurses in training the fourth series of lectures for trained nurses was also given during the winter, the attendance having been very large. The total number of patients admitted to the Convalescent House, Corstorphine, had been 1199, as against 1192 in 1910. The daily average was 64·46 Of the total number admitted 964 remained three weeks or more. The total income of the Convalescent House for the year was £2570 5*s*. 5*d*., of which £2096 12*s*. 3*d*. was extraordinary revenue, and the expenditure amounted to £2835 15*s*. During the year the financial position of the Convalescent House and its relation to the Royal Infirmary had been considered by the board, and it had been found on examining old records that the house had been originally gifted "on condition that it should become an integral part of the infirmary and be kept in connexion with it." The board had, therefore, decided (1) to discharge the overdraft on the bank account as at Sept. 30th, 1910, amounting to £10,795, by a cross entry against the general fund of the infirmary; (2) to charge any debit balance at the end of each financial year thereafter against the general fund of the infirmary; and (3) that in the event of there being surplus revenue in any year the same should be "ear-marked," retained, and invested for the endowment of the Convalescent House. The accounts will, as formerly, be kept separate from those of the infirmary. In July, 1911, the Royal Infirmary was honoured by a visit from Their Majesties the King and Queen. The wards visited were No. 7 surgical, under the charge of Professor Caird, and No. 30 medical, under the charge of Dr. Byrom Bramwell and Dr. G. A. Gibson. The experiment in the treatment of incipient cases of mental disease which had been undertaken for one year in response to an application from the parish council had proved so far successful. Sixty-five cases of this nature had been admitted (25 males and 40 females). Of these, 30 were sent home recovered, 14 were discharged as improved. 3 remained *in statu quo*, 13 were certified, 3 died, and 2 remained under treatment. The physician in charge of the ward for incidental delirium, where the cases were treated, stated in his report that while the experiment had worked satisfactorily he did not consider that this ward, owing to the nature of some of the other cases dealt with as well as to the want of opportunities for recreation and out-door amusement, was the most suitable place for such treatment. The parish council subsequently inquired whether additional accommodation could be furnished pending the acquisition by them of a suitable institution for the treatment of such cases. The managers were reluctantly compelled to reply that they were unable to provide extended facilities, but intimated their readiness to meet the wishes of the council should they have any male cases urgently requiring treatment. The infirmary during the year had sustained the loss through death of several medical men closely connected with the work of the institution. Of former members of the staff there had died Dr. Andrew Smart, Dr. Peter Hume Maclaren, and Dr. Joseph Bell, the two last of whom had also rendered valuable service to the infirmary on the board of management. The death of Dr. Alexander Bruce had occurred while he held the post of ordinary physician to the infirmary, and after years of service which began in 1885, when he was appointed pathologist to the institution. The managers also deplore the death of the late superintendent of the infirmary, Colonel W. P. Warburton, C.S.I., which took place less than three months after he retired from office. In succession to Colonel Warburton the managers had appointed Lieutenant-Colonel Sir Joseph Fayrer, Bart., M.D., R.A.M.C. (retired), who entered on his duties on August 1st, having been for a month before that in daily association with his predecessor in the various departments of the work. Finally, the managers express anxiety as to the effect of the working of the National Insurance Act, and appeal to their fellow citizens to see to it that the splendid work of the Royal Infirmary be not impaired should any voluntary contributions be diverted from its support in consequence of the passing of this Act.

Milk-supply Regulations.

In a recent lecture on Milk and Human Tuberculosis the veterinary surgeon to the corporation of Glasgow enunciated his views on the control of our milk-supply. He stated that the Government had done practically nothing to safeguard the public health from tuberculous milk. In 1899 the Local Government Board amended the Dairies, Cowsheds, and Milkshops Orders so as to include tuberculosis of the udder, but they did not empower local authorities to slaughter the animals found to be affected. The consequence was that a dairyman who found that one of his animals was diseased simply passed it on to his neighbour. If the public wanted a pure and wholesome milk-supply the matter lay entirely in their own hands. They must demand that the Government take the necessary steps, and they must keep pressing that demand. He summarised his proposals as follows: (1) Withdrawing the power at present possessed by local authorities to frame regulations under the Dairies, Cowsheds, and Milkshops Orders; and (2) establishing a central authority to promote and maintain a pure and wholesome milk-supply. The advantages of placing the supervision and control under a central authority were obvious. It would take this all-important matter out of the hands of indifferent and, it might be, interested local authorities, and at the same time every cowkeeper would be enforced to conform to requirements applicable to the whole country. These requirements must provide, in addition to others, for (*a*) the annual licensing of every building used as a cowshed or dairy; (*b*) the seizure of milk grossly contaminated with filth; (*c*) the frequent examination by a veterinary surgeon of every milch cow; (*d*) the compulsory notification by the owner, or person in charge, of every diseased cow; and (*e*) the immediate slaughter of every cow affected with tuberculosis of the udder.

IRELAND.

(FROM OUR OWN CORRESPONDENTS.)

Honours for Irish Medical Men.

TWO medical men in Ireland are included in the list of New Year honours, both of whom receive knighthoods—viz., Sir J. Hawtrey Benson, President of the Royal College of Physicians, and Sir B. C. A. Windle, President of University College, Cork.

The Medical Inspection of Schools.

The subject of medical inspection of schools in Ireland is attracting more public attention than hitherto. Mr. J. B. Story discussed it recently in a lecture before the Statistical and Social Inquiry Society of Ireland. With regard to diseases of the eye, he stated that on every day that he saw out-patients in the Eye Dispensary he saw one or more children with some contagious form of eye disease, and there was no officially-arranged method of excluding them from school. Indeed, except for his certificate, which he was under no obligation whatever to give, the parents would be prosecuted if the children did not attend school. Every oculist in Dublin who had studied the question must have seen persons whose sight had been permanently injured by disease contracted from their school-fellows in National, industrial, or charitable schools. He estimated that the medical inspection of Irish schools would cost about £23,000, which could be raised by a rate of three-eighths of a penny in the pound.

The Irish Branch of the British Dental Association.

The Lord Lieutenant, speaking at the annual dinner of the Irish Branch of the British Dental Association, stated that medical inspection of schools was absolutely needed. To obtain it, the essential thing was to create a public opinion in its favour, and the means would then be provided. Many of the other speakers spoke of the anomaly of the Legislature in exacting certain requirements of knowledge and skill for the efficient practice of dentistry and neglecting to secure that practice to those certified as possessing such knowledge and skill.

The Poor-law Service.

It is becoming an increasing difficulty to obtain suitable candidates for many of the Poor-law appointments in Ireland. At a recent meeting of the Gorey board of guardians only one application was received for the vacant medical officership of Camolin, advertised at £120 per annum, with the usual emoluments. The applicant wrote stating that he would accept the position only on the salary being increased to £150. When called before the board, he pointed out that he would have to pay in rent £20, to keep a horse and man £60, which would leave £40 to live upon. The private practice was worth about £50 a year. It was decided to advertise again. The way to compel the guardians to give adequate salaries is to let their medical vacancies go seeking candidates.

The Medical Libraries of Ireland.

It is a matter of difficulty to anyone engaged in scientific work to know where he can most readily obtain access to such records as he may wish to consult. Those in charge of the medical libraries of the two Royal Colleges in Dublin have done their best to make their stores available to inquirers, but neither library has funds sufficient to keep complete files of even the most important periodicals. A few years ago the librarian of the Royal College of Surgeons issued a list of the medical journals taken in the various libraries in Dublin. This prevented much loss of time in fruitless search. The registrar of the Royal College of Physicians, with the help of Mr. Phelps, the librarian of the College, to whose courtesy all medical readers in Dublin are indebted, has recently issued a complete list of all foreign medical periodicals taken at any of the medical libraries in Ireland. This list also gives notes of the back numbers preserved. As there are in all 12 public libraries which take medical journals, the list will prove very serviceable in showing where particular periodicals are to be found. The library of Trinity College files all journals published in the United Kingdom.

The School of Physic Celebrations.

The bicentenary celebration of the School of Physic, Trinity College, has been fixed for July 4th, 5th, and 6th, 1912. Guests from many universities and medical corporations are to be invited. A provisional programme of the celebration has been arranged. It includes various receptions, garden-parties, and banquets, as well as university functions, at which honorary degrees will be conferred on distinguished visitors. A representative committee of medical graduates to coöperate in the celebrations will shortly be appointed. A meeting of graduates will be held in Dublin at an early date. It is hoped to get together an exhibition of objects, documents, and books connected with the history of medicine in Ireland.

The Belfast Water-supply.

The Belfast water commissioners have announced their intention of introducing a Bill next session to obtain an extension of time—from 1913 to 1925—for the construction of the Silent Valley storage reservoir on the Kilkeel river in the Mourne mountains, and to provide the necessary borrowing and rating powers of £500,000 for the works. It is proposed to increase the available rating power from 1*s.* 8*d.* to 2*s.*

The Insurance Act.

At a meeting of the board of management of the old age fund of the Presbyterian Church of Ireland, held in Belfast on Dec. 21st, 1911, a committee was appointed to examine the provisions of the National Insurance Act, with the view of the formation of an approved society under the Act for members of the Presbyterian Church in Ireland.

Pomeroy Dispensary.

The Local Government Board has written to the Cookstown board of guardians adhering to its previous communication that the initial salary of the medical man to be appointed to Pomeroy Dispensary be £100, as fixed by the guardians' scale of December, 1909. The guardians had appointed Dr. W. J. F. Mayne some weeks ago, at a salary of £80 a year, on the understanding that a midwife would be appointed at £20. The board of guardians has decided to adhere to its action and to keep the salary at £80.

Sanitary State of Omagh.

The Local Government Board has sent to the Omagh urban council extracts from the report of the medical officer of health regarding the condition of the urban district which show that nuisances have not been abated and that the district is not in a good sanitary condition. Fault is found with the water-supply, which contains peaty matter due to defective filtration and dirty pipes. Many of the sewers are defective, and the streets insanitary. The medical officer of health stated that his recommendations to the urban council on important matters had not been carried out and that the sanitary by-laws were not enforced. The report has been referred to the public health committee for consideration.

Omagh Asylum.

Five further cases of typhoid fever have been reported from this institution.

Down District Asylum.

In his annual report of this asylum the medical inspector draws attention to the fact that the number of patients had fallen from 767 to 753 at his last visit, which shows that this institution was an exception to the general rule that the number of insane requiring care is increasing in Ireland. The asylum could provide for about 70 more than it at present contains.

Diphtheria at Larne.

At a meeting of the Larne urban council held on Jan. 1st special acknowledgment was made of the humane and thoughtful act of Lady Dixon, who on the breaking out of diphtheria last year instructed the chairman to inform the medical men that she would supply antitoxin serum for all patients not in a position to pay for it.

PARIS.

(FROM OUR OWN CORRESPONDENT.)

Rhythmic Respiration to Prevent Breathlessness.

AT the Academy of Medicine, on Dec. 19th, 1911, M. Manquat communicated a method for obviating the breathlessness that ensues from rapid or uphill walking. It consists in maintaining the rhythm and speed rate of respiration within physiological limits, by utilising the natural powers of control over the respiratory and expiratory muscles. The rhythm and physiological speed rate maintain the cardio-vascular circulation in proper condition. The respiration can be rhythmically adjusted to the pace, by prolonging the expiration over about twice as many paces as the inspiration, and making not more than from 18 to 20 complete respiratory cycles in a minute. This method is also an excellent educative and therapeutic

measure, for it makes it possible to modify the breathlessness whenever the latter is dependent on any cardio-pulmonary trouble; under such conditions, however, it should be utilised with much circumspection and in a progressive manner.

Threats of Death to a Medical Man.

A recent incident recalls a drama which in the spring of the past year saddened the French medical profession—I refer to the assassination of Dr. Guinard by a disappointed patient. Some time ago M. Bosc, a sufferer from emphysema, was admitted to the Hôpital de la Pitié in the service of Dr. Babinski. On his becoming convalescent the administration of the hospital, having a demand for the bed occupied by him, requested him to return home. M. Bosc complied, but with great dissatisfaction. He presently wrote a letter to Dr. Babinski, in which he gave vent to his discontent, and reminded him of the fate that befell Dr. Guinard. Dr. Babinski prosecuted him in the Correctional Tribunal, and M. Bosc has been awarded a long sentence.

The Sale or Lottery of Eatables in the Fêtes Foraines.

The prefect of police of the Seine has issued a decree relative to the sale or putting up to lottery of eatables at *fêtes foraines*. This decree, in view of the fact that the sale or lottery of eatables susceptible of spoiling or decay presents a danger to the public health, forbids the sale or raffling at the *fêtes foraines* of meat, chickens, fish, shell-fish, preserves, or any other eatables except confectionery or pastry. Offenders will be tried before the ordinary police tribunal.

Antityphoid Vaccination.

In a communication to the Academy of Medicine on Dec. 19th, 1911, Professor Chantemesse referred to the question of antityphoid vaccination, the great value of which has been demonstrated by the experience of the army of occupation of Morocco. There is no room any longer for doubt as to its efficacy. Vaccination against typhoid fever has attained the same status as that against small-pox, and, above all, the vaccines put forward as a consequence of the labours undertaken 25 years ago by M. Chantemesse and M. Vidal in the laboratory of Professor Cornil, have given us this precious discovery. From that time M. Chantemesse has employed as a vaccine a culture of typhoid bacilli killed by heat. The later modifications of this technique have consisted of little else than changes of temperature employed in the heating of the culture or the addition of an antiseptic. Moreover, the results obtained with the vaccine of M. Chantemesse or its derivatives have proved comparable with those in the Moroccan campaign, for instance, in which four different types of vaccine have been used. There is no need for further experiment. In the American army 43,000 soldiers have been vaccinated during the last 18 months. The reaction that followed the operation has usually been insignificant. It was noteworthy in only one case in a thousand. Out of 43,000 cases of vaccination there were in all only four cases of typhoid fever, all of which were cured. Quite recently 15,000 soldiers of the army of Texas, mobilised on account of the troubles on the Mexican frontier, have been compulsorily vaccinated. In all, two cases of typhoid fever occurred, and these were followed by cure. Vaccination against typhoid fever is now obligatory in the American army. M. Chantemesse has installed at the Hôtel Dieu a service of gratuitous vaccination, which medical practitioners, internes, students, patients, and the public frequent daily in large numbers.

Therapeutic Applications of Colloidal Rhodium.

M. d'Arsonval has reported to the Academy of Sciences that as the result of investigations conducted at the Hôpital de la Pitié M. André Lancieu has succeeded in preparing colloidal rhodium in a perfectly stable form, having also a constant composition and a granular structure almost uniform and of extreme minuteness. Electric currents of high voltage and high frequency were the means employed in producing it. This colloidal solution has been used with much success in the treatment of a number of cases, often apparently hopeless and all of them the result of infection, including cases of pneumonia, typhoid fever, puerperal fever, and malaria. The administration was always by small injections, the pyrexia always subsided very regularly, and no mishaps ever occurred.

Death of Professor Lannelongue.

Professor Lannelongue died on Dec. 21st last, on the day after he relinquished the presidency of the Academy of Medicine, at the age of 71. His death took place in three days from the onset of pulmonary congestion. Professor Lannelongue was not only a surgeon of great ability, he was also, in every sense of the word, a great man. Having attained at a very early age the rank of *agrégé* of the Faculty of Medicine and surgeon to the Paris hospitals, he took charge during the siege of Paris of the ambulance station at the Luxembourg, which was organised by Madame Remusat, who subsequently became his wife. A member of the Academy of Medicine at 43, a professor at 45, he was a member of the Institute, President of the Academy of Medicine, Deputy, and finally Senator. He presided in 1900 over the International Congress of Medicine, which was for him the occasion of the donation of an important prize, and in the same year he founded in his native town, to which he bequeathed in advance his own house for this purpose, a popular museum of art. He was essentially a man of ingenuity. The ideas that he was enabled to put into actual operation, the methods that he worked out, will perpetuate his name in history more even than his career in the professorial chair at the faculty or his service at the hospital. As a surgeon he was an inventor even more than a practitioner, while his unwearying and active benevolence, his dedication of himself daily to public work, necessarily alienated a large part of his time from the practice of medicine. He founded the Institution for the Protection and Rehabilitation of Young Girls, the Dispensary Hospital Marie Lannelongue, in memory of his admirable wife, and also the establishment for young convalescent girls at Epinay-sous-Sénart.

Jan. 2nd.

BERLIN.

(FROM OUR OWN CORRESPONDENT.)

The Mysterious Epidemic of Poisoning in Berlin.

ON the morning of Dec. 27th it became known that in the municipal shelter for the homeless (Städtisches Obdach) 15 men had suddenly died with symptoms of poisoning and that some 20 more had become so seriously ill with the same symptoms that they had to be conveyed to the Friedrichshain Hospital. The above-named shelter is a refuge for people having no abode, who are admitted there without any formality for the night. The shelter is opened at sunset, actually at 4 P.M., and there are beds and bathing accommodation, and an evening meal, consisting of soup and bread, is supplied. The shelter is destined for men only; for homeless families a municipal shelter exists in another building. Apart from the municipal asylum there is a shelter in another quarter of the city, supported by private means, which receives men and single women in separate wings under nearly the same provisions as the municipal shelter. The latter has an accommodation for about 4000 people, and is especially overcrowded in the winter season. In the neighbourhood of the shelter is a street traffic of cheap comestibles, which the people are accustomed to buy for their suppers in addition to the soup supplied by the authorities, and it was first believed that the poisoning was caused by food purchased by the men outside the shelter. But this traffic had been prohibited on Dec. 26th and the two preceding days, because of Christmas and Sunday, so that this suspicion was abandoned. It was stated, however, that on the evening of Dec. 26th a man had sold within the shelter a box of red herrings to his fellows, and it was suggested that this box was stolen by him in the central market hall, where it had been thrown away as unfit for sale because the fish was spoiled. The symptoms resembled those of grave poisoning. According to the daily papers the patient suddenly felt very ill, had general convulsions, and soon fell into a state of apathy which led to a fatal issue within a few hours. A post-mortem examination was performed in two cases by Professor Strassmann, director of the Institute of Legal Medicine, the result being that the cause of death could not be ascertained, only some hæmorrhage in the intestinal mucosa being found. The bacteriological research also proved to be without result, and

the presence of an epidemic disease, such as cholera or cerebro-spinal meningitis, was disproved. The shelter was therefore opened the following evening as usual and no further case was expected. The morning papers of Thursday, however, reported 36 cases of death and 70 cases of illness. The authorities then took energetic measures. Five medical men were put on night duty in the shelter, and two motor cars for the transport of patients to the hospitals were ordered to wait within the court of the shelter during the night. The event proved the necessity for these measures, for on the following evening also new cases happened. A rumour circulated in the city that the poisoning was due to the soup distributed on behalf of the authorities, and this was expressly suggested by the Fishmongers' Association, which drew attention to the fact that only inmates of the asylum had been taken ill, and that within its knowledge no epidemic of poisoning by spoiled fish had broken out hitherto in Berlin. But the municipal authorities showed that the evening meal had not been supplied until 8 P.M. as usual, whilst the first cases had occurred at 6 P.M. On the evening of Thursday there appeared to be a decrease in the number of cases, but, on the other hand, cases now began to be reported from outside the asylum. In the neighbourhood of Berlin, of three men who had spent the night in a barn two suddenly died with the same symptoms of poisoning. This event caused great alarm, because it was believed that an infectious disease had now spread from the shelter to the outside. It was ascertained, however, through the evidence of the third man that the deceased had spent the last night in the shelter. The same was the case with some other seizures which occurred in the streets or police stations. On Dec. 31st 137 cases were registered, of which 68 have since died, and a great number are in a hopeless state in hospital. Two pavilions in the Friedrichshain Hospital have been exclusively reserved for new cases. The police are on duty in the shelter to examine the patients as to where they spent the last few hours or days, whence they got their meals, and so on, but owing to the apathetic condition of the patients it is exceedingly difficult to get any trustworthy replies. Moreover, the men belong to the very poorest and semi-criminal class and are little inclined to give to the police full particulars as to their life. In a number of cases the deceased are totally unknown, so that they were photographed on behalf of the police, and dactyloscopy was used for purposes of identification. Specimens of foods also from the grocers in the neighbourhood of the shelter were taken and examined. But notwithstanding the work of the medical officers it has so far been impossible to ascertain the nature of the disease. Professor Gaffky is of opinion that it is caused by intoxication with the bacillus botulinus, but the source of the poisoning is still absolutely unknown. According to the papers of this morning (Dec. 31st) the authorities no longer believe that the poisoning was due to spoiled food, but attribute it to cognac spoiled by methyl alcohol. Whether this extraordinary and improbable statement is correct it is impossible at present to say, but so great is the interest in the events at the shelter that the wildest rumours get abroad. It must be hoped that the source of the poison may be discovered as soon as possible, so that this epidemic of poisoning—one of the most extensive on record—may be checked.

Vital Statistics and Public Health in Prussia.

The annual report on the health of the kingdom of Prussia has now been published by the medical department of the Government. According to an epitome which has appeared in the *Aerztliche Sachverständigen-Zeitung*, the report states that the number of births has again decreased, being 21,253 less than in the preceding year, the rate being 32 living births for each 1000 of the population; this is the minimum since 1901, when the decline in the birth-rate first began, and has continued ever since. In 1876 the birth-rate was 40·9 per 1000, but in 1901 it was 36·5 per 1000. It is worth noting that the eastern districts, especially those inhabited by Poles, have far the highest birth-rate, whilst the lowest birth-rate is in Berlin—namely, 22·5 per 1000. The number of marriages has remained almost unaltered, but the number of children of each marriage has fallen. The death-rate has decreased from 18·03 per 1000 in the year 1908 to 17·1 per 1000 in the year 1909, so that notwithstanding the decreased birth-rate the population has become greater by 581,258, being an increase of 15 per 1000. The over-population of Germany continues to be a serious problem for the country. The principal causes of death were senile marasmus, diseases of the gastro-intestinal canal, especially in infants, tuberculosis, pneumonia, and diseases of the heart and blood-vessels. Among the exceptional causes of death there were 8422 cases of suicide, 876 of murder or manslaughter, 14,534 of fatal accidents, and 1096 of death attributable to alcoholism. The mortality of infants was 30·6 per cent. of the general death-rate. The city of Barmen in Rhenish Prussia had the lowest death-rate for infants and Berlin had the highest. On the subject of infectious diseases the report states that scarlet fever and diphtheria were increasing to some extent, while enteric fever, dysentery, and cerebro-spinal meningitis were decreasing. Some cases of cholera were registered in places near the Russian frontier. Pneumonia and influenza were prevalent during the inclement season in certain districts. Compulsory disinfection worked fairly well, although disinfection was sometimes neglected for personal reasons. There were 409 registered disinfectors. Vaccinations and revaccinations were performed in 1,941,988 cases; 30 deaths occurred as a result of vaccination, 15 of them being caused by local infections, such as erysipelas or cellulitis, and by generalised vaccinia; in 113 cases slighter troubles happened, so that altogether there were only 7 unfavourable complications per 100,000 vaccinations. The prevalence of venereal diseases could, of course, only be estimated as far as hospital patients were concerned; the number of cases has remained almost unaltered, being 47,474 as compared with 46,327 in the preceding year. In Berlin the incidence of venereal diseases was considerably over the average, being 63·9 per 10,000 of the population. The death-rate from tuberculosis has decreased, being only 15·6 per 10,000, as compared with 26·7 per 10,000 in the year 1891. Of 100 deaths in the year 1891 there were 11·6 caused by tuberculosis, but in 1909 the corresponding proportion was only 9·11. There were 230 cases of hydrophobia with 8 deaths, the mortality therefore being 3·48 per cent., notwithstanding the Pasteur treatment. Appendicitis proved fatal to 2128 persons. The number of deaths by poisoning was 1387, of which 592 were cases of accident, 772 were cases of suicide, and 23 were cases of murder. Among the accidental poisonings 47 per cent. were due to the effects of carbonic oxide, and among the suicides 28·5 per cent. resulted from poisoning by lysol. Death was due to morphine in 25 cases of suicide and 15 accidental poisonings. In the section dealing with public hygiene the results of the supervision of the sewers, sanitary arrangements, and water-supply by the local medical officers of health are reported. Special importance is attached to the providing of hygienic and cheap dwellings, and philanthropic associations for encouraging the construction of such dwellings were supported by the local authorities. The inspection of the food-supply was one of the principal duties of the medical officers of health, who worked in connexion with the public laboratories. There were 83 State or municipal laboratories in which 226,425 samples of food, exclusive of drinking water, were examined. In 27,729 cases, being 12·2 per cent. of the total, the quality of the food was unsatisfactory. It is remarked that the extreme dearness of butcher's meat has led to the consumption of rabbits and of horseflesh in some districts. In several samples of so-called fruit-juice not a trace of fruit was present, whilst, on the other hand, some beverages described as non-alcoholic were found to contain up to 3·5 per cent. of alcohol. The dangers of alcoholic excess were illustrated by the fact that 7528 inebriates were conveyed to the public asylums. Inebriety is reported even in the case of schoolboys principally in Berlin, in some places in the east of Prussia, and in some factory districts. The temperance societies are commended as doing good work by establishing places for the sale of tea and coffee in factories, in mines, and in districts where over-indulgence in spirits was prevalent. On the whole, the abuse of spirituous liquors was steadily diminishing, but the excessive smoking of cigarettes was obviously on the increase, as already stated in the health report of the Imperial Navy. The number of hospitals was 3153, of which 2278 were general hospitals with 15,459 beds, where 1,222,063 patients were treated, the average stay in hospital being 30 days. The number of qualfied

medical men was 19,319; there were also 1789 qualified dentists and 4008 mechanical dentists (Zahntechniker). The nursing profession included 41,473 persons, 80 per cent. of them being women, who in the rural districts belonged for the greater part to ecclesiastical orders. It is stated that the latter class of nurses often engage in unqualified medical work. The number of pharmacies was 3453, all provided with licences arranged in three classes, and in addition to them there were 217 pharmacies established within and for the special use of hospitals. The report is a very elaborate one, and deserves the careful attention of all who are interested in public hygiene.

Legislative Proposals Relative to Unqualified Medical Practice.

After having been twice brought before Parliament the Bill relating to unqualified practice has again been dropped because of the closing of the Parliamentary session. It was after the first reading referred to a committee of the House, as mentioned in this column in THE LANCET of July 9th, 1911, and at this stage of its progress some members moved that if unqualified practice is done away with then medical men should be liable to punishment if they declined to attend patients who sought their advice. The Government disapproved of this proposal, but declared itself willing to ask the opinion of the medical chambers on that question. Obviously the above amendment was only intended to delay the passing of the Bill, and its Parliamentary opponents have succeeded so far that it will have to be reintroduced for the third time in the next session. In view of the forthcoming Parliamentary election, the *Deutsche Medizinische Wochenschrift* advises medical men to ask candidates whether they are favourable to the suppression of unqualified medical practice, and to vote only for candidates giving an answer in the affirmative.

Dec. 31st, 1911.

NOTES FROM SOUTH AFRICA.

(FROM OUR OWN CORRESPONDENT.)

The South African Memorial to King Edward VII.

THE appeal for subscriptions to establish an Order of Nurses in South Africa in commemoration of King Edward VII. is not meeting with the success that was anticipated. Nevertheless, a considerable sum has been received, and it is confidently expected that the committee presided over by Lady Gladstone will be in a position soon to bring forward definite proposals. A congress of Boer women, known as the "Zuid Afrikaanse Vrouwen Federatie," was recently held in the Transvaal, and Lady Gladstone took the opportunity of writing to the congress with the view to obtain its support for the scheme. The matter was discussed, and a resolution passed which seems to indicate that racial feeling cannot be eliminated in South Africa, even in connexion with a project for the alleviation of human suffering. The resolution was as follows:—

> The Zuid Afrikaanse Vrouwen Federatie feels the great necessity of such an institution for South Africa, more especially with regard to the country districts, particularly residents on farms, and would gladly give their hearty support to the establishment thereof, provided such institution be established in a true South African spirit with a purely South African Board, and this to be confirmed by a constitution. The Federatie expects all officials and nurses of the institution to be South African (Dutch and English), i.e., either born in this country or who have resided here for a period of not less than five years, and who are fully conversant with the nature, manners, and languages of the people. The Federatie strongly objects to imported nurses, since, in the absence of such knowledge, the relation between nurse and probationer or patient will be strained, and result in mutual dissatisfaction. The Federatie further takes exception to the following clause in the proposed constitution: "District nursing will constitute a subordinate part in the duties of the nurses," being of the opinion that nursing in towns is fairly satisfactory, though badly neglected in the country districts, resulting in the loss of many a valuable life.

The inferences to be drawn from the resolution are, first, that the Federatie objects to members of the Governor-General's family or staff being connected with the scheme, for at present the only two persons connected therewith not born in the country, or not having resided therein for five years, are Lady Gladstone and the honorary secretary, who is a member of the Governor-General's staff; and, secondly, that English-trained nurses are not wanted. The committee's reply to the Federatie has not been published, and, indeed, it is difficult to see what suitable reply could be made without administering a severe snub. It is quite certain that it will be impossible to comply with the wishes of the Federatie, for it is doubtful whether sufficient South African-trained nurses can be secured. Apart from this, it is certain that not more than 20 per cent. of locally trained nurses are able to speak the Dutch language. The last portion of the resolution is apparently due to a misunderstanding as to the meaning of "district nursing," the Federatie having taking it to mean nursing in the rural as opposed to the urban areas. The Federatie would doubtless place a knowledge of the Dutch language amongst the members of the nursing staff above a knowledge of professional work. It is to be sincerely hoped that this resolution will not deter Lady Gladstone from pressing on with the good work.

Proposed Hospital Legislation.

In addressing the guests of the Mayor of Cape Town at a luncheon given to the delegates to the Congress of Cape Municipalities the other day, Sir Frederic de Waal foreshadowed a provincial ordinance to reform the system under which grants by the State have hitherto been made to the public hospitals, to rectify other abuses that require attention, and particularly to direct public charity into a more reasonable channel. Considerable curiosity has been caused by this announcement; it is, however, generally welcomed, as for a number of years past it has been recognised by the profession and by hospital managers that the present system of financing and managing the hospitals of the province is most unsatisfactory.

Friction at the Johannesburg Hospital.

Mr. Rissik, the administrator of the Transvaal, has at length stepped in and and appointed a Commission to inquire into the friction which exists between the board of the Johannesburg Hospital and the honorary medical staff, and to report what action is required in order to end an unseemly squabble drawn out over a long period. The Commissioners consist of Dr. F. A. Arnold, the medical officer of health of the Transvaal, Mr. H. J. Hofmeyr, ex-mayor of Johannesburg, and Mr. M. Nathan. It would have been fairer had the medical member been drawn from some other part of South Africa, for presumably General Smuts consulted Dr. Arnold, who was then medical officer of health of the Transvaal, before he inaugurated the system which has been at the root of the present trouble. However, the appointment of any Commission at all is welcomed, and the medical staff have elected a committee consisting of Dr. G. A. E. Murray, Dr. H. H. Currie, Dr. Bauman, and Dr. S. Y. van Niekerk to present their case to the Commission. The findings of the Commission will be awaited with no little interest.

Ward v. Hertzog.

The first stage has been reached in the law courts in connexion with the libel action brought by Dr. A. B. Ward, President of the Orange Free State Medical and Pharmacy Council, against General Hertzog, the Minister of Justice. The defendant excepted to the plaintiff's declaration regarding certain alleged defamatory words uttered by him at two public meetings, one held at Smithfield and the other at Fauresmith, as bad in law and as disclosing no cause of action, and the grounds upon which he based this exception are: (1) that there was nothing in the words alleged that showed that they referred to the plaintiff; and (2) that the words themselves were not defamatory. The Judge President in the course of a long summing up disallowed the exception with costs, but leave to appeal was granted.

The late Sir Charles O'Grady Gubbins.

On every side regrets and sympathy are expressed for the death of Sir Charles O'Grady Gubbins, which took place recently at Newcastle, in Natal. The newspapers unite in paying a tribute to the personal affection inspired by the deceased Minister, whose death removes one of the most genial and attractive personalities from the arena of South African politics. Whilst he had a distinguished professional career in Natal, it is since the war as a politician that perhaps he is best known. He held for several years up to the date of Union the portfolio of Colonial Secretary of Natal and Minister in Charge of Public Health. It was largely due to his influence that Natal agreed to enter the Union. Since Union he has been a Member of the Cabinet, but without portfolio. Some weeks ago he became ill—a victim to internal cancer, but throughout his illness he maintained up to the last, in spite of his sufferings, his cheery Irish wit and humour. During the week before his death he was

visited by numbers of friends, most of whom in the heyday of his activities were associated with him in the politics of the country. Amongst these may be mentioned Senator Hitchins, the Hon. A. T. Oliff (late Colonial Treasurer of Natal), Colonel Greene (late Minister of Railways), Sir Frederick Moor (late Prime Minister), and the Hon. T. Watt, while only a few days before his death General Botha, the Prime Minister, journeyed specially to Newcastle to bid him farewell. His death was characterised by uncomplaining resignation, and his genial personality and restraining influence will be sorely missed in the Cabinet and in the Senate. When Sir Charles took to politics the medical profession gained in Natal prestige it never had before, and by his death at the present critical juncture it has lost the friend on whom it felt it could most surely rely in the Union Cabinet. The deceased graduated in medicine in Dublin in 1878.

The Defence Bill.

The long-expected South African Defence Bill has been published. Provision is made for practically universal training of Europeans and the complete assumption locally of responsibility for the defence of South Africa, a responsibility hitherto shared to a large extent with the Imperial Government.

Town Planning Bill.

A Bill to regulate the conditions under which townships may be established upon public or private property has been published. This Bill is apparently to be administered by the Minister of Lands. It is an absurd little Bill, and doubtless will never become law in its present form. It entirely overlooks the real objects which should be aimed at in such a measure—namely, the possibility of a good water-supply, easy means of drainage, suitability of soil, climate, &c. The Bill seems essentially a measure that should be introduced and given effect to by those in charge of the Local Government and health of the country, and in the absence of a properly constituted Central Health Department would far better have been left to the various Provincial Governments.

Conference of Government Health Officers.

A conference was held recently at Durban between the medical officer of health for the Union and the assistant medical officers stationed at Cape Town and Durban respectively. It is understood that the object of the conference was to endeavour to secure uniformity of port health administration at the different ports of the Union. Already the all-time port health officer at Cape Town has been replaced by a part-time practitioner engaged in an extensive private practice, and it will be interesting to note whether any further steps are to be taken to demolish safeguards that were considered of paramount importance prior to Union in preserving the health of the people.

Obituary.

I have to record with regret the deaths of two well-known practitioners—namely, Dr. A. J. Westby of Beaufort West, and Dr. W. A. Rutherford of Mafeking. The former graduated at Trinity College, Dublin, in 1878. He was a well-known athlete, and played cricket for the Gentlemen of Ireland and for Trinity as a student; and also for Ireland in international Rugby football. In 1894 he settled in Beaufort West, and was appointed district surgeon in 1898, which post, in conjunction with that of medical officer of health to the municipality, he held till his death. Dr. Rutherford had for many years held the post of medical officer to the Bechuanaland Protectorate Police. Both these gentlemen will be sadly missed. A movement is on foot to endow a bed at the New Somerset Hospital in memory of Dr. Westby, and as a token of the respect felt for him in the district where he had worked so long.

Dec. 1st, 1911.

NOTES FROM INDIA.

(FROM OUR OWN CORRESPONDENT.)

Durbar Delhi.

YOUR readers, I am sure, would like to have a few words about the place where Their Imperial Majesties are staying at this date. I have called it Durbar Delhi. It was some eight months ago a vast desert outside the old Mogul city of Delhi. To-day it is a medley of a World's Fair Exhibition, Earl's Court Exhibition, Epsom Downs on Derby Day, with glimpses of South Kensington thrown in. Miles of broad avenues have been well laid out with roads rendered absolutely dustless by thorough oiling, and going off on either sides of these avenues are broad spaces occupied by the camps of Indian chiefs and Government officials. Every chief has had a large *shamiana* erected as a reception camp, which has been variously decorated and gorgeously furnished. I observed that the grounds around the various camps were beautifully laid out in gardens of flowers and lawns, which were freshly green, thanks to the numerous irrigation channels which were specially made. Electric lights, Chinese lanterns, fairy lamps, torches, &c., all added to the beauty of the newly made city of tents. Driving through the avenues and roads one passed all sorts and conditions of people of all the nations under the sun, and these were either on foot or in motor-cars of various size and shapes, phaeton gharries, tum-tums, landaus, tongas, brakes, ekkas, and country carts, not to speak of State carriages attended by bodyguards. The place was extremely well policed, well traversed by telegraph posts, amply provided with post-offices, specially protected against fire by tall fire-alarm stations at various parts overlooking the whole area and connected by telephone to each other, each of which station had a Merryweather fire-engine, and the whole area was traversed by a light railway with numerous little stations. The outstanding feature in all this well-organised planning was the absence of any urinals, latrines, and lavatories for European and educated Indian ladies and gentlemen. The place was besieged by thousands of European ladies and gentlemen for the day's outing, and many of these had awkwardly to seek the private bathroom tents of officers and others which were convenient at the time. There were heaps of latrines of a crude description for the native servants of the various camps and for the troops, and incinerators of an old pattern giving out their constant smoke were near, and most improperly protected against the view of the travellers in the light railway. When one states that the area of the camping grounds was nearly as large as London, and that practically the whole of this area was taken up by camps amply separated from each other by lawns, the reader may draw for himself the picture of the whole. The amphitheatre deserves mention, as it is the place from which the King-Emperor was proclaimed. It is about three times the size of the Herculanean amphitheatre, and though they had been working at it for months the absence of European supervision showed itself in the fact that up to the time for the proclamation the Indian in charge had not arranged the decorations and carpeting. But the city of tents was a sight worth seeing, and the like of it will not be seen for centuries.

Dec. 13th, 1911.

Medical News.

UNIVERSITY OF CAMBRIDGE.—At examinations for medical and surgical degrees held in Michaelmas term, 1911, the following candidates were successful:—

FIRST EXAMINATION (*October, 1911*).

Part I., Chemistry.—K. Atkin, Jesus; C. N. Carter and H. W. Featherstone, Trinity; L. S. Gatherwood, Sidney Sussex; A. A. Gemmell, King's; E. A. Grylls, Caius; N. S. Hewitt, Sidney Sussex; H. C. Hopkinson, Emmanuel; B. E. Jerwood, Sidney Sussex; C. M. Jones, Downing; A. H. Pearce, Clare; R. M. Savur, non-collegiate; C. G. Schurr, Caius; C. H. Vernon, St. John's; and V. Wilkinson, Christ's.

Part II., Physics.—K. Atkin, Jesus; C. N. Carter, Trinity; H. B. Dodwell, Emmanuel; J. S. Eloff, Trinity Hall; H. W. Featherstone, Trinity; E. A. Fiddian, Emmanuel; H. G. Galbraith, Caius; L. S. Gatherwood, Sidney Sussex; A. A. Gemmell, King's; E. A. Grylls, J. H. Gulliland, and W. F. T. Haultain, Caius; H. D. Y. Herries, Trinity; N. S. Hewitt, Sidney Sussex; H. C. Hopkinson, Emmanuel; B. E. Jerwood, Sidney Sussex; C. M. Jones, Downing; F. Moor, Trinity; E. S. Orme, Queen's; A. H. Pearce and C. G. Schurr, Caius; F. N. Sidebotham and R. O. Sternberg, Clare; B. H. Swift, Caius; C. H. Vernon, St. John's; G. H. Ward, Caius; and V. Wilkinson, Christ's.

Part III., Elementary Biology.—S. L. Bhatia, Peterhouse; H. Chell, St. John's; H. G. Galbraith, Caius; H. D. Y. Herries, Trinity; H. C. Hopkinson, Emmanuel; B. E. Jerwood, Sidney Sussex; C. G. Schurr, Caius; R. O. Sternberg, Clare; C. H. Vernon, St. John's; V. Wilkinson, Christ's; and A. G. P. Wills, Corpus Christi.

FIRST EXAMINATION (*December, 1911*).

Part I., Chemistry.—B. P. Ayre, Jesus; W. T. Beswick, Trinity

Hall; W. H. Blackburn, Christ's; C. V. Braimbridge, Downing; W. S. Brown, Caius; F. T. Burkitt, Christ's; G. E. Burton, Clare; A. E. Clark-Kennedy, Corpus Christi; L. Cunningham, Downing; I. de B. Daly and U. de B. Daly, Caius; J. C. Davies, Trinity; H. B. Dodwell, Emmanuel; C. G. Edwards, Caius; W. Fenwick and E. A. Fiddian, Emmanuel; H. G. Galbraith, J. H. Gulliland, and W. F. T. Haultain, Caius; A. D. Y. Herries, Trinity; S. C. Ho, St. John's; F. Moor, Trinity; E. S. Orme, Queen's; F. N. Sidebotham and R. O. Sternberg, Clare; B. H. Swift, Caius; G. B. Tait, King's; G. S. Taylor, Sidney Sussex; A. A. Thomas, Christ's; A. R. Walker, Emmanuel; G. H. Ward, Caius; W. T. Warwick, B.A., Emmanuel; H. G. E. Williams, King's; and R. A. Woodhouse and R. S. Woods, Downing.

Part II., Physics.—B. P. Ayre, Jesus; G. H. Bickley, Pembroke; J. F. J. Blanchard, Emmanuel; C. E. Bond, Caius; C. V. Braimbridge, Downing; W. S. Brown, Caius; F. T. Burkitt, Christ's; A. E. Clark-Kennedy, Corpus Christi; L. Cunningham, Downing; I. de B. Daly and U. de B. Daly, Caius; J. C. Davies, Trinity; S. R. E. Davies, Queens'; J. M. Downie, Christ's; W. L. Emtage, Queens'; W. Fenwick, Emmanuel; E. O. Goldsmith, Pembroke; E. W. Nichol, Caius; G. W. Pratt, St. John's; E. G. Snaith, Magdalene; G. B. Tait, King's; G. S. Taylor, Sidney Sussex; R. R. Traill, Trinity; A. C. Walker, Caius; A. R. Walker and W. T. Warwick, B.A., Emmanuel; R. C. P. Whitcombe and H. G. E. Williams, King's; and R. A. Woodhouse and R. S. Woods, Downing.

Part III., Elementary Biology.—C. G. Ainsworth, B.A., Downing; C. E. Bond and W. S. Brown, Caius; L. Cunningham, Downing; I. de B. Daly, Caius; H. W. Featherstone, Trinity; E. A. Fiddian, Emmanuel; L. S. Gathergood, Sidney Sussex; A. A. Gemmell, King's; W. F. T. Haultain, Caius; N. S. Hewitt, Sidney Sussex; E. W. Nichol, Caius; P. R. O'R. Phillips, Pembroke; F. N. Sidebotham, Clare; E. G. Snaith, Magdalene; B. H. Swift, Caius; R. R. Traill, Trinity; W. T. Warwick, B.A., Emmanuel; R. A. Woodhouse and R. S. Woods, Downing.

SECOND EXAMINATION (*October, 1911*).

Part II., Pharmacology and General Pathology.—W. G. Bigger, B.A., Queens'; H. J. Bower, B.A., Emmanuel; E. C. Bradford, B.A., Pembroke; J. Brewer, B.A., Emmanuel; I. M. Brown, B.A., Downing; E. H. P. Brunton, B.A., Trinity; L. B. Clarke, B.A., Emmanuel; G. M. Cowper, B.A., Trinity; J. L. Davies, Emmanuel; K. B. Dickson, B.A., Trinity; E. L. Dobson, B.A., King's; J. M. Evatt, B.A., Caius; W. D. Galloway, Clare; C. H. M. Gimlette, B.A., Caius; W. B. Gordon, B.A., Clare; C. H. Gow and N. Gray, B.A., Emmanuel; R. J. Hearn, B.A., Jesus; C. Helm, B.A., King's; A. M. Humphry, Trinity; B. L. Hutchence, B.A., Caius; R. W. P. Jackson, Clare; J. S. Kennedy, B.A., King's; S. D. Kilner, B.A., Emmanuel; H. H. Mathias, B.A., King's; J. B. Matthews, B.A., Clare; S. C. Miskin, Emmanuel; O. G. Morgan, B.A., Clare; W. New, B.A., Downing; A. V. O'Keeffe, Sidney Sussex; H. G. Oliver, B.A., R. A. Peters, B.A., and R. S. Scott, B.A., Caius; L. E. S. Sharp, Trinity; W. H. Shephard, B.A., Christ's; A. G. Shera, B.A., Emmanuel; L. R. Shore, B.A., St. John's; A. C. S. Smith, Trinity; W. S. Soden, B.A., St. John's; E. W. Todd, B.A., Trinity; R. L. M. Wallis, B.A., Downing; G. C. Wells-Cole, B.A., Caius; and F. A. Williamson, B.A., Queens'.

SECOND EXAMINATION (*December, 1911*).

Part I., Human Anatomy and Physiology.—J. C. Andrews, St. John's; G. L. Attwater, B.A., Pembroke; L. W. Batten, B.A., Sidney Sussex; G. A. G. Bonser, B.A., St. John's; J. C. Bramwell, Trinity; H. F. Brice-Smith, B.A., St. John's; W. E. H. Bull, B.A., Caius; H. R. Buttery, B.A., Christ's; A. B. Buxton, Trinity; M. Chadwick, B.A., St. John's; G. F. Clifton, B.A., Downing; G. R. E. Colquhoun, Trinity; A. C. M. Coxon, B.A., Magdalene; E. C. Cunnington, B.A., Corpus Christi; E. D. D. Davies, B.A., Christ's; A. N. Drury, Caius; H. Dunkerley, B.A., Downing; H. S. Evans, Trinity; E. Forrester-Paton and L. S. Fry, B.A., King's; H. A. C. Goodwin, B.A., Jesus; E. H. H. Granger, Clare; C. Grantham-Hill, Caius; W. T. Hare, B.A., Christ's; J. B. Hunter, St. John's; J. H. Jordan, B.A., Emmanuel; H. D. Lander, B.A., Caius; F. C. Lapage, B.A., King's; H. W. Leatham, Trinity; A. H. Little, Corpus Christi; H. D. McCall, B.A., Christ's; E. C. Malden, Caius; R. A. Mansell, Emmanuel; C. G. T. Mosse, Caius; D. F. A. Neilson and W. D. Newcomb, Trinity; W. Oats, B.A., Caius; H. B. Padwick, Emmanuel; H. R. Pollock, B.A., Trinity; S. R. Prall, Emmanuel; W. B. Purchase, B.A., Sidney Sussex; G. D. Read, B.A., St. John's; W. H. C. Romanis, Trinity; T. H. Somervell, Caius; G. E. Spicer, Trinity; and H. N. Stafford, A. R. S. Warden, and E. Watson-Williams, Caius.

THIRD EXAMINATION (*December, 1911*).

Part I., Pathology and Pharmacology.—M. Avent, B.A., Caius; H. M. McC. Coombs, B.A., Emmanuel; R. Gamlin, M.A., King's; H. K. Griffith, B.A., Trinity; A. N. Hodges, B.A., Queens'; R. M. Miller, M.A., Clare; C. G. H. Moore, B.A., Caius; R. S. Morshead, B.A., Trinity; G. M. Parker, B.A., Emmanuel; C. H. G. Philp, B.A., St. John's; and V. T. P. Webster, B.A., Emmanuel.

Part II., Surgery, Midwifery, and Medicine.—The following have now satisfied the examiners in all three sections:—L. A. P. Anderson, B.A., and J. H. Baldwin, M.A., Emmanuel; A. M. Bodkin, B.A., King's; W. J. Carr, B.A., Trinity; F. G. Chandler, B.A., Jesus; H. M. McC. Coombs, B.A., Emmanuel; W. D. Coplestone, M.A., Jesus; M. Donaldson, B.A., Trinity; C. A. Dottridge, B.A., Clare; E. A. Dyson, B.A., Jesus; A. G. Evans, B.A., Trinity; G. V. Fiddian, B.A., Downing; A. W. Gaye, B.A., and A. H. Gosse, M.A., Caius; H. K. Griffith, B.A., Trinity; A. E. Herman, B.A., King's; A. C. Jepson, B.A., Pembroke; G. G. Johnstone, B.A., King's; N. F. Lock, B.A., Caius; A. J. McNair, B.A., Emmanuel; J. C. Marklove, B.A., and R. A. Ramsay, B.A., Caius; W. D. Ross, B.A., King's; H. B. G. Russell, B.A., Sidney Sussex; W. A. Russell, B.A., Emmanuel; A. W. Stott, M.A., Trinity; and J. F. Taylor, B.A., H. Selwyn.

UNIVERSITY OF LONDON.—At examinations held in December, 1911, the following candidates were successful:—

M.D. EXAMINATION.

Branch I., Medicine.—Charles Anthony Basker, B.S., Guy's Hospital; Muriel Constance Bywaters, B.S., London (Royal Free Hospital) School of Medicine for Women; James Alfred Patrick Cullen, London Hospital; David Morgan Davies, B.S., Charing Cross Hospital; Ivor Jones Davies, B.S., St. Bartholomew's Hospital and University College, Cardiff; Trevor Berwyn Davies, B.S., University College Hospital; Gopal Vinayak Deshmukh, B.S., London Hospital; Edward Cecil Brearey Ibotson, B.S., and William Johnson, B.S., Guy's Hospital; Charlotte Alice King, B.S., London (Royal Free Hospital) School of Medicine for Women; Norman Claudius Lake, B.S., B.Sc. (University medal), Charing Cross Hospital; Elias Leopold Woolf Mandel, B.S., Guy's Hospital; and Horace Richard Wilson, B.S., University of Liverpool.

Branch II., Pathology.—Arthur Davies, B.S., Westminster Hospital and London School of Clinical Medicine; and Emily Helen Morris, B.S., London (Royal Free Hospital) School of Medicine for Women.

Branch IV., Midwifery and Diseases of Women.—James Bruce-Bays, M.D., B.S., St. Mary's Hospital; Gladys Margaret Campbell Dunbar, B.S., and Mabel Emily Gates, B.S., London (Royal Free Hospital) School of Medicine for Women; Herbert Cubitt Lucey, B.S., and William Henry Miller, B.S. (University medal), Guy's Hospital; Florence Muriel Morris, B.S., and Helen Irene Moss, B.S., London (Royal Free Hospital) School of Medicine for Women; and Alfred Geddes Tresidder, B.S., London Hospital.

Branch V., State Medicine.—Tom Shadick Higgins, B.S., B.Sc., University College Hospital.

Branch VI., Tropical Medicine.—Hugh Stannus Stannus (University medal), St. Thomas's Hospital and London School of Tropical Medicine.

M.S. EXAMINATION.

Branch I., Surgery.—Joseph Ebenezer Adams, St. Thomas's Hospital; Ernest William Charles Bradfield, St. Mary's and St. Bartholomew's Hospitals; Edward Kenneth Martin, University College Hospital; Harry Platt, Victoria University of Manchester; and David Ranken, University of Durham and St. Bartholomew's Hospital.

FIRST EXAMINATION FOR MEDICAL DEGREES.

Pass List—John Arnold Molony Alcock, Guy's Hospital; John Struan Alexander, University College; Hannah Katherine Alton, King's College; Colin Reinhardt Andrew, St. Paul's School; Keith Edward Attenborough, St. Mary's Hospital; Robert Townly Bailey, King's College; Geoffrey Thomas Baker, Middlesex Hospital; Charles Douglas Banes, Hartley University College; Walter Ralph Barrett, The Leys, Cambridge, and London Hospital; Edward Vincent Beaumont, St. Mary's Hospital; Joseph Warwick Bigger, Trinity College, Dublin; John Archibald Binning, University College; Constance Marie Briggs, University Tutorial College and Girton College; Harold George Broadbridge, London Hospital; Louis Abel Celestin, Royal College, Mauritius, and University Tutorial College; Julien David Constantin, St. Bartholomew's Hospital; Ronald Campbell Cooke, St. Thomas's Hospital; Dermot Dominic Randal Dale, St. Bartholomew's Hospital; Raghunath Ganesh Dani, University College; John Milton Davey, University of Leeds; *†Leonard Snowden Debenham, St. Paul's School and Guy's Hospital; Allen Roy Dingley, St. Bartholomew's Hospital; Charles Yarrow Eccles, St. Thomas's Hospital; *Stanley Harold Edgar, University College, Nottingham; Edwin Francis Fernando, University of Edinburgh and University College; Thomas Richard William Francis Figg-Hoblyn, Guy's Hospital; William Fletcher-Barrett, Birkbeck College; Marjorie Ellen Franklin, London (Royal Free Hospital) School of Medicine for Women; William Lawson Mabson Gabriel, University of Leeds; Aziz Girgis, London Hospital; Lorel Goodfellow, London (Royal Free Hospital) School of Medicine for Women; Hugh Morgan Gray and John William Hawksley Grice, Guy's Hospital; †¶Arnold Guy Harsant, St. Paul's School and London Hospital; Thomas Lowthian Heath, Guy's Hospital; Norman Hammond Hill, University of Leeds and St. Bartholomew's Hospital; Harry Mainwaring Holt, University of Leeds; George Philip Buckingham Huddy, London Hospital; David Bruce Stewart Jones, Charing Cross Hospital; Francis Reginald Law, University of Leeds; Herman Lewis, London Hospital; Katharine Lloyd, London (Royal Free Hospital) School of Medicine for Women; Douglas Loughlin and Sydney Alan Stormer Malkin, University College; Francis Keene Marriott, London Hospital; Arthur Harry Morris, University of Bristol; John Kerr Muir, Middlesex Hospital; John James Murphy, Sinnethamby Muttiah, and David Forsyth Parton, London Hospital; Eleanor Joyce Partridge, London (Royal Free Hospital) School of Medicine for Women; Robert Louis Portway, Guy's Hospital; Christopher George Schurr, Gonville and Caius College, Cambridge; Elisabeth Henrietta Schwab, Bedford College and London (Royal Free Hospital) School of Medicine for Women; Nirendra Mohan Sen-Gupta, London Hospital; Charles Ernest Alan Shepherd, King's College; Harold Gane Stormer, St. Thomas's Hospital; Raymond Stowers, University College; *Edward Cowper Tamplin, Pharmaceutical Society's School and St. Thomas's Hospital; Frederick Alfred Unwin, Birkbeck and King's Colleges; William John Vance and Samuel Vidot, Guy's Hospital; Josephine Leigh Hunt Wallace, University College; John Woollaston Wayte, St. Thomas's Hospital; William Ronald White-Cooper, St. Bartholomew's Hospital; and †George Cuthbert Nelson Younger, Middlesex Hospital.

* Awarded a mark of distinction in Inorganic Chemistry.

† Awarded a mark of distinction in Physics.

¶ Awarded a mark of distinction in General Biology.

N.B.—This list, published for the convenience of candidates, is issued subject to its approval by the Senate.

SOCIETY OF APOTHECARIES OF LONDON.—At examinations held in December, 1911, the following candidates passed in the subjects indicated:—

Surgery.—R. E. Clarke (Sections I. and II.), King's College Hospital; P. J. Montgomery (Sections I. and II.), Middlesex Hospital; and J. E. Taylor (Sections I. and II.), Leeds.

Medicine.—R. E. Clarke (Sections I. and II.) and D. E. S. Davies (Sections I. and II.), King's College Hospital; L. K. Edmeades (Section II.), Guy's Hospital; W. G. Fraser (Sections I. and II.), McGill; J. G. Lewis (Section I.), Newcastle; G. Meyer (Section I.), Graz; P. J. Montgomery (Sections I. and II.), Middlesex Hospital; F. C. Shone (Section II.), University College Hospital; and A. J. Tozer (Sections I. and II.), St. Mary's Hospital.

Forensic Medicine.—R. E. Clarke, King's College Hospital; H. Rimington, St. Bartholomew's Hospital; H. Robinson, Manchester; and H. G. Steel and A. J. Tozer, St. Mary's Hospital.

Midwifery.—E. M. Brand, Royal Free Hospital; R. E. Clarke, King's College Hospital; and H. Robinson, Manchester.

The Diploma of the Society was granted to the following candidates, entitling them to practise medicine, surgery, and midwifery:—R. E. Clarke, D. E. S. Davies, and P. J. Montgomery.

LONDON SCHOOL OF TROPICAL MEDICINE.—At the examination at the end of the thirty-seventh session (October–December, 1911) the following students were successful:—

*Captain W. D. Wright, I.M.S.; *C. F. Simpson; B. A. Percival (Colonial Service); W. Turner; E. J. Quirk (Colonial Service); J. W. Tomb; J. W. Thomson (Colonial Service); R. Semple (Colonial Service); M. Salih; L. Sammy; P. L. Craig; Miss L. E. Watney; R. Willan (Colonial Service); W. B. A. Moore (Colonial Service); E. J. Powell (Colonial Service); M. Graves (Colonial Service); W. Browne (Colonial Service); S. Goodbrand (Colonial Service); W. A. Nicholson (Colonial Service); H. Ostrom; Miss M. Pantin; R. Mugliston (Colonial Service); D. C. Robertson; G. Girgis El-daba; J. G. Morgan (Colonial Service); E. Ward (Colonial Service); C. H. Crooks; and N. Mahrus.

* With distinction.

VICTORIA UNIVERSITY OF MANCHESTER.—At examinations held in December, 1911, the following satisfied the examiners:—

FINAL M.B. AND CH.B. EXAMINATION.

K. D. Bean, L. W. Howlett, W. H. Laslett, S. E. McClatchey, Newton Matthews, H. G. Peake, James Walker, and William Warburton.

Obstetrics.—Frank Oppenheimer and R. P. Stewart.

Medicine.—Frank Oppenheimer.

Forensic Medicine and Toxicology.—F. S. Bedale, C. L. Graham, and T. H. Oliver.

THIRD M.B. EXAMINATION.

General Pathology and Morbid Anatomy.—Allan Barrett, *F. A. Bearn, J. G. Bennett, E. S. Brentnall, C. H. Crawshaw, H. N. Crossley, H. F. Hutchinson, Harold Kempsey, *T. P. Kilner, Eugene Leahy, C. G. Lees, F. L. Newton, T. P. Robertson, Harold Sheldon, *A. V. Stocks, Ernest Talbot, Cornelius Thompson, H. W. F. Williams, and G. W. Wood.

Pharmacology and Therapeutics and Hygiene.—F. C. Bentz, W. R. Blore, F. S. Charnock, H. C. Duffy, Harold Kempsey, Roderic McGill, Gladys H. Ramsden, H. A. Sandiford, F. K. Tomlinson, and C. H. Whittall.

Pharmacology and Therapeutics.—H. S. Gerrard.

SECOND M.B. AND CH.B. EXAMINATION.

‡Lily Allan, J. C. P. Bayley, Basil Browning, Frank Chadwick, J. W Craw, A. T. Gibb, ‡D. T. Harris, †J. R. Jagger, O. M. de Jong, J. D. Kenyon, E. A. Linell, †Clara A. Lomas, Kate K. May, Kamil Maximus, A. S. Paterson, W. A. Rogerson, J. R. B. Russell, E. H. Walker, and Henry Wilson.

FINAL B.D.S. EXAMINATION.

T. A. B. Corless.

DIPLOMA IN DENTISTRY (FINAL EXAMINATION).

Harry Lyth, L. W. Ward, and R. S. Ward.

Dental Prosthetics and Operative Dentistry.—Robert Ramsbottom and D. H. Sutton.

THIRD B.D.S. EXAMINATION.

C. F. Scott.

DIPLOMA IN DENTISTRY (THIRD EXAMINATION).

H. V. Brown, T. C. Cregan, H. O. Hatton, E. R. Lamb, Kate Latarche, D. J. O'Brien, Eric Renshaw, E. B. Ryley, Harold Walker, and Ernest Ward.

* Distinction in Pathology.
† Distinction in Anatomy.
‡ Distinction in Physiology.

UNIVERSITY OF LEEDS.—At examinations held recently the following candidates were successful:—

M.B. AND CH.B., SECOND EXAMINATION.

Part I., Anatomy and Physiology.—W. D. Anderton, S. N. Cohen, J. J. Digges La Touche, H. Foxton, F. King, W. H. Lonen, H. W. Robinson, H. Sochet, J. Wilkinson, and C. Wilson.

FINAL EXAMINATION.

Part I.—L. H. Butler, L. Dunbar, F. H. Kitson, K. Menon, J. J. Pickles, H. P. Shackleton, H. Sinson, and J. Wright.

DIPLOMA IN DENTAL SURGERY.

First Professional Examination.—J. E. Gill.

DIPLOMA IN PUBLIC HEALTH.

Part I.—G. O. Chambers and H. F. Horne.
Part II.—C. C. Pickles.

The degrees of Bachelor of Medicine and Bachelor of Surgery were conferred upon the following candidates:—

A. L. Bastable, *H. Caplan, J. B. T. Keswick, C. J. H. Little, G. E. Macvie, F. W. Nunneley, *W. Robinson, *J. B. Sinson, *J. P. Walker, and F. Wigglesworth.

* Second-class honours.

UNIVERSITY OF EDINBURGH.—At a graduation ceremonial held in the M'Ewan Hall on Dec. 20th, 1911, the following degrees were conferred:—

Doctor of Medicine.—Angus Graham Macdonald, James Forbes Mackay, and Hubert Andrew David Moore.

Bachelor of Medicine and Master in Surgery.—Edward Francis Coghlan.

Bachelor of Medicine and Bachelor of Surgery.—Joseph Reginald Aeria, John Edwin Allan, Albert Alexander Atkinson, Wallace Rutherford Bayne, Percy William Page Bedford, Delvine Bell, Robert Bertram Blair, Arthur Bloom, Niels Höegh Brönnum, Cecil Burnham, Robert Carlyle Carlyle, Alexander Bruce Cheves, Anna Chose, Guillaume Jacobus Cillie, Jacob David Malan Claassens, Disney Hubert Dusch Cran, Reginald Wynyard Davies, Robert Cecil Dickson, Alexander Erskine Drynan, William Ernest FitzGerald, Joseph Geoghegan, John Marchbank Gillespie, Charles William Graham, Gilbert Malise Graham, Malcolm Claud Russell Grahame, John Victor Livingstone Grant, James Gray, John William Gray, George Harrison, Arthur Christopher Heard, Kenneth Goodall Hearne, John Hewat, Janette Theresa Hill, Hugh James Hopps, Abraham Jassinowsky, Cicely Mary Kerby, Stefanus Gottfried Kriegler, Archibald Langwill, George Leggat Leggat, Thomas Lindsay, Patrick M'Cool, William Smail M'Laren, Archibald Browning Mitchell, Michael Joseph Paris, Randolph James Elliot Paterson, Bindeshwari Prasad, Maxwell Ramsay, Frederick William Rayment, Spence Daer Reid, Mossie Rougvie, Robert Glen Shaw, Leslie Henderson Skene, Sahib Singh Sokhey, Jacobus Johannes Stander, Henry Hay Stewart, Lawrence Ramsay Thomson, Frederick Livingstone Tulloch, Peter Vieyra, Charles Derwent Walker, Chung Ching Wang, Harry Whitaker, and Robert Burton Meikle Yates.

Diploma in Tropical Medicine and Hygiene.—John Alexander and Charles Edward Southon.

The Milner-Fothergill gold medal in Therapeutics has been awarded to Dr. John Tait.

Dr. George Foy has been elected an honorary member of the State Medical Association of Georgia, U.S.A.

DEATHS OF EMINENT FOREIGN MEDICAL MEN.—The deaths of the following eminent foreign medical men are announced:—Dr. B. Eads, formerly professor of anatomy and physiology in the Rush Medical College, Chicago.—Dr. H. C. Dalton, formerly professor of surgery in the Marion Sims College of Medicine, St. Louis.—Dr. N. R. Coleman, formerly professor of medicine in Ohio Medical College, Columbus.—Dr. Adam Szulislawski, honorary professor of ophthalmology in Lemberg, aged 46.—Dr. Karl Hörmann, *privat-docent* of gynæcology and *oberarzt* of the University Gynæcological Clinic in Munich.—Dr. P. Topinard, formerly professor in the Paris School of Anthropology.—Dr. E. Bornet, member of the Academy of Sciences, Paris.

UNIVERSITY OF LONDON: UNIVERSITY COLLEGE.—Work in the Faculty of Medical Sciences at University College will be resumed on Tuesday, Jan. 9th. The Provost will be in attendance on Monday, Jan. 8th, from 10 to 1 for the purpose of seeing students who desire to be enrolled. A course of Page-May Memorial Lectures will be delivered at University College by Dr. Henry Head, F.R.S., on Fridays at 5 P.M., beginning on Jan. 26th, and in connexion with the Francis Galton Laboratory for National Eugenics two lectures on Sir Francis Galton will be delivered by Professor Karl Pearson on Tuesdays, Jan. 30th and Feb. 6th, at 8.30 P.M., to be followed on subsequent Tuesdays by a course of six lectures on Some Problems of Eugenics. Full particulars of the above courses may be obtained on application to the secretary of University College.

CENTRAL MIDWIVES BOARD.—A meeting of the Central Midwives Board was held at Caxton House, Westminster, on Dec. 21st last, Sir Francis H. Champneys being in the chair. A letter was considered from the Local Government Board forwarding copies of extracts from the annual reports for the years 1909 and 1910 of the medical officer of health for the Wantage rural district calling attention to the inadequate supply of midwives in the district and the cause thereof. The Board directed that the Local Government Board be thanked for its letter. A letter was considered from

Mr. C. E. Paget, medical officer of health of Northamptonshire, reporting, in accordance with the provisions of Rule F.2, that he had advised a district nurse, who practises midwifery, to abstain from practice as a midwife for a period of 14 days after complete disinfection of herself, her clothing, and her appliances by reason of her having been in contact with a case of scarlet fever for a period of 18 days. Letters were also considered from Dr. W. J. Howarth, medical officer of health of Kent, reporting the suspension of one midwife for 11 days, and of another for 12 days, in similar circumstances. The Board directed that Mr. Paget and Dr. Howarth be thanked for their letters, and that they be informed that the Board approves of their action in the circumstances stated. A letter was considered from Dr. H. Handford, medical officer of health of Nottinghamshire, reporting the suspension of a midwife for 14 days. The Board directed that Dr. Handford be thanked for his letter, and that he be informed that the Board approves of his action in the circumstances stated. The secretary was further directed to communicate with the local supervising authority, pointing out that the matter appeared to disclose a *primâ facie* case of negligence and misconduct against the midwife, and asking the authority whether it so found, and to furnish evidence in support of the statements contained in the letter. A letter was considered from an approved midwife at Norwich requesting the Board to reconsider its decision not to recognise a local medical practitioner as a teacher because of the difficulty she experiences in obtaining theoretical instruction for her pupils from the recognised teachers of the Norwich Maternity Charity. The Board directed that the applicant be referred to the medical staff of the Norwich Maternity Charity, who have been recognised by the Board as teachers for the purpose of giving the necessary theoretical instruction to candidates proposing to enter for the Board's examinations from Norwich and the surrounding district. A letter was considered from the medical officer of health of Birkenhead calling attention to the difficulty of successfully prosecuting uncertified women practising as midwives owing to the difficulty of proving that the practice is for "gain" as required by Section 1 (2) of the Midwives Act, 1902. The Board directed that the medical officer of health of Birkenhead be thanked for his letter, and that a copy thereof be forwarded to the Privy Council. The secretary reported that a false and fraudulent certificate of birth had been tendered to him by a woman desirous of becoming a candidate for the examination of Dec. 15th. The Board directed that the papers be placed in the hands of the Director of Public Prosecutions, and that he be requested to take such action in the matter as he may think fit.

UNIVERSITY OF LIVERPOOL.—During the past session the students entering in the faculty of medicine have been divided as follows: 24 have entered for the degree of the University, 3 for degrees in other universities, 2 for the diploma of the London Conjoint Board, and 6 for those of other examining bodies. The entries of the last six years show the total number of students at present in the faculty as the largest reached—viz., 148, classified as follows:—First M.B., 27; Second M.B., 28; Final M.B., 48; First Conjoint, 2; Second Conjoint, 10; Final Conjoint, 8; other degrees and qualifications, 25; making a total of 148. Students other than undergraduates are as follows:—Research, 41; School of Hygiene, 31; Tropical School, 49; operative surgery, 3; dental, 64; making a total of 188. The total of all classes is 336. The examination results have been as follows: First M.B., Part I., 34 presented, 15 referred; Part. II., 28 presented, 5 referred. Second M.B., Part A, 18 presented, 4 referred; Part B, 10 presented, 3 referred. Final M.B., Part I., 24 presented, 5 referred; Part II., 27 presented, 5 referred; Part III., 26 presented, 12 referred. Four candidates submitted theses for the M.D., three successfully. Twenty-three candidates presented themselves for the Diploma in Public Health, of whom 9 were referred. Thirty-four candidates presented themselves for the Diploma in Tropical Medicine, of whom 5 were referred. The course of instruction in systematic surgery has for the first time been divided into general and regional. The medical faculty has devoted considerable attention to the proposal to institute degrees in hygiene. A diploma in ophthalmic surgery has been instituted for graduates, and ordinances and regulations relative to it have been approved by the Council and Senate.

BOOKS, ETC., RECEIVED.

ALLEN, GEORGE, AND COMPANY, LIMITED, Ruskin House, 44 & 45, Rathbone-place, London, W.

THE Chief Inspector of Factories, Home Office, London, S.W., gives notice of vacancies as Certifying Surgeons under the Factory and Workshop Act at Kelvedon, in the county of Essex; at St. Austell, in the county of Cornwall; and at Clara, in King's County.

Births, Marriages, and Deaths.

BIRTHS.

ALLEN.—On Jan. 1st, at Harley-street, London, W., to Dr. and Mrs. R. W. Allen, a daughter.

ATKINS.—On Dec. 27th, 1911, at Loughborough, Leicestershire, the wife of Frank Robert Lowth Atkins, M.R.C.S., L.R.C.P., of a daughter.

DAVIS.—On Dec. 27th, 1911, at C. M. S., Amritsar, the wife of Rev. G. Brocklesby Davis, M.D., of a son.

ELLIS.—On Dec. 28th, 1911, at Bonchurch, I.W., the wife of Francis Heygate Ellis, M.R.C.S., L.R.C.P. Lond., of Salisbury, Rhodesia, of a son.

GRAHAM.—On Dec. 26th, 1911, at "The Cottage," Porchester-road, Newbury, to S. D. Graham, M.B., and Agnes M. Graham, twin daughters.

MARRIAGES.

PINCHING—WOODWARD.—On Dec. 27th, 1911, at St. Cuthbert's, Kensington, William Guy Pinching, M.R.C.S., L.R.C.P., to Dorothy Mary, second daughter of the late Harry Woodward, Solicitor, and Mrs. Woodward.

DEATHS.

AITCHISON.—On Dec. 31st, 1911, at Drayton-terrace, South Kensington, after a short illness, Charles Umpherston Aitchison, M.D., aged 36.

WOLFF.—On Dec. 26th, 1911, at Harborne-road, Edgbaston, Birmingham, Alfred Wolff, M.R.C.S., in his 59th year.

N.B.—A fee of 5s. is charged for the insertion of Notices of Births, Marriages, and Deaths.

Notes, Short Comments, and Answers to Correspondents.

TRYPANOSOMIASIS IN NYASALAND.

ACCORDING to the "Diary" issued by Dr. A. H. Barclay, acting principal medical officer of the Nyasaland Protectorate (Part XV., Oct. 12th, 1911), the total number of cases of trypanosomiasis in which trypanosomes had been found was 55, of which 9 were then under treatment at Ngani Camp. There were no admissions to the camp during August and September. One case has died at the camp since the last report. The remedies tried have been salvarsan, soamin, and atoxyl, the latter alone and in combination with hydrarg. perchlor., but no case has shown any improvement under treatment, so that the patients are beginning to regard death as the result of treatment rather than of disease, and are becoming very refractory to the intramuscular injections. No arsenophenylglycin has so far been available for trial. The general conclusion seems to be that no treatment is of any avail in cases which have reached the cachectic stage, though atoxyl in conjunction with other drugs still offers some hope of ultimate success. In a paper received from Dr. H. S. Stannus, of the Nyasaland Protectorate, and Dr. Warrington Yorke, of Liverpool, on the Pathogenic Agent in a Case of Human Trypanosomiasis in Nyasaland, these gentlemen conclude that the trypanosome concerned is the T. rhodesiense, probably a new species, and that as Glossina palpalis has not been found in Nyasaland, some other insect, possibly Glossina morsitans, is the carrier, which is supported by the experimental infection of six monkeys in Tanganyika. No transmission experiments have been tried at this station. A site for the Royal Societies' Commission laboratories has been selected on Kasu Hill, and buildings are in process of erection under Captain A. E. Hamerton, D.S.O., R.A.M.C.

HOT.

To the Editor of THE LANCET.

DEAR SIR,—Kindly publish what I saw in print some time ago.

"*Sure Cure for Cold and Influenza.*—½ or ¼ teaspoonful cayenne pepper in a glass hot milk drunk as hot as sufferer can bear (Personally tried and found successful with cold. Have not since I saw it had influenza to try it with) and make above public in America and elsewhere *as it is every one's business to save valuable human life at once.*"

Yours, &c.,
ALTRUIST.

Dec. 26th, 1911.

MR. DENMAN ON REVOLVER CARRYING.

Mr. Denman had recently before him at Marborough-street police court the case of a foreigner described as a tailor with an address in Whitechapel, who on being arrested for an offence in Hyde Park, was found to be armed with a loaded revolver. Mr. Denman said, "Ever since I became a magistrate I have been a voice crying in the wilderness, and I hope that some day a Bill of five lines will be introduced making the carrying of firearms an offence which can be summarily dealt with. As it is the cumbersome proceeding of a solemn meeting of the London County Council has to be gone through before a prosecution can take place. ..... I hope that a private Member will introduce a Bill to the effect that if any person is found carrying a revolver he will be liable to fine or imprisonment." What Mr. Denman has cried in the wilderness THE LANCET has reiterated in print, but there is little or no chance of a private Member of Parliament, as he suggests, being able to get a Bill of such a nature through in the present circumstances of legislation. It is a matter for the Home Secretary to undertake, and the police might then be trusted to render the law effective by laying their hands upon plenty of criminals who habitually go about armed. The prosecution by the County Council referred to above is, of course, for the offence of carrying firearms without a gun licence.

INCOME-TAX DEMANDS.

To the Editor of THE LANCET.

SIR,—The collectors' demand notes which are annually thrust upon the attention of taxpayers at a time when they have so many other claims upon their pockets are now either delivered or in course of delivery.

While it may be too late to get the amount of the gross assessment reduced your readers should give the following points their careful attention and see to it:—

1. That they have been allowed the full statutory abatement by reason o their incomes not exceeding £700.

2. That in addition to the usual abatement they have been allowed off the assessment £10 for each child under 16 by reason of their income not exceeding £500.

3. That they have been allowed for life assurance premiums.

4. That in the case of incomes over £5000 they are only charged super-tax upon the amount of the income in excess of £3000.

5. That they understand what they are paying, and if they have paid too much take steps at once to obtain repayment.

Claims for repayment can now in many cases be made for three or even four years.—We are, Sir, yours faithfully,

THE TAX ADJUSTMENT (SCARFF'S) AGENCY.

171, Strand, London, W.C.

COBRA VENOM: A QUERY.

To the Editor of THE LANCET.

SIR,—We would be greatly obliged if any of your readers could tell us the name of the scientific laboratory or philanthropic society that has offered a prize or reward to the person who should discover an antidote for the "cobra" bite. A short while back a notice appeared in an English paper to the effect that a prize was offered for the discovery of such an antidote. We are, Sir, yours faithfully,

GRACE BROTHERS & Co., LTD.

144, Leadenhall-street, London, E.C., Dec. 27th, 1911.

A PORTABLE SPITTOON.

Messrs. W. Martindale, of New Cavendish-street, London, W., have placed on the market a portable spittoon of new design which has several features to commend it. The vessel is made of polished white metal, and measures 3 inches in depth and 2½ inches and 1 inch respectively across the long and short axes of the ends. The lid is kept in place by a simple screw adjustment, which forces a rubber washer against the rim of the spittoon, thus making the vessel watertight. Internally there is the usual funnel-shaped receptacle. There is nothing unsightly in the appearance of the spittoon, which when closed looks something like a rather thick cigarette case. The price is 10*s.* 6*d.*

TRAUMA AND APPENDICITIS.

Dr. H. A. Ballance (Norwich) inquires for references to monographs, contributions to journals, &c., upon the subject of trauma as a cause of appendicitis. He does not want references to text-books, and he is already aware of the contribution in the *Annals of Surgery*, 1901, Vol. XXXIII., p. 387, by Robinson, of Chicago.

WITH reference to a paragraph in THE LANCET of Dec. 9th, 1911, p. 1665, Mr. Frederick Dixon writes to say that the Christian Science Home in New York, referred to by our local correspondent, is a private enterprise for which the Christian Science Church assumes no responsibility.

COMMUNICATIONS not noticed in our present issue will receive attention in our next.

A DIARY OF CONGRESSES.

WE shall publish this diary from time to time that our readers may have under their hands the dates of the approaching scientific Congresses. It is unnecessary to issue the lists of all these functions week by week, and we propose to make only such gatherings as will occur in the immediate future the subject of regular announcement. The following Congresses, Conferences, and Exhibitions are announced for the next few months:—

Jan. 3rd–10th (University of St. Petersburg).—Second Congress of Pure and Applied Chemistry and Physics (in honour of the late Dr. I. Mendeléef).
,, 20th–27th (Hong-Kong).—Second Biennial Congress of the Far Eastern Association of Tropical Medicine.
Feb. 13th–14th (London).—Central Poor-Law Conference.
March 7th–11th (Berlin).—Thirty-third Balneological Con ress.
March 23rd–April 4th (London, Royal Agricultural Hall).—International Smoke Abatement Exhibition.
,, (London).—First Congress of Pure Food and Health Society of Great Britain.
April 1st–7th (Tunis).—Twenty-second Congress of French-speaking Alienists and Neurologists.
,, 8th–13th (Rome).—Seventh International Congress of Dermatology and Syphilology.
,, 8th–15th (Johannesburg).—Thirteenth South African Medical Congress.
,, 14th–20th (Rome).—Seventh International Congress on Tuberculosis.
,, 15th–18th (Wiesbaden).—Twenty-ninth German Congress for Internal Medicine.
,, (Giessen).—Congress on Study of Families, Inheritance, and Race Hygiene.
Spring (London).—Second Optical Convention.

The following journals, magazines, &c., have been received:—Sei-i-Kwai Medical Journal, Practitioners' Journal (Russian), L'Hygiène, The Child, Annales de l'Institut Pasteur, Archives de l'Institut Pasteur de Tunis, Bulletin de la Société de l'Internat des Hôpitaux de Paris, Archives de Médecine et Pharmacie Navales, New Zealand Medical Journal, Canadian Medical Association Journal, Archives of Internal Medicine, Yellow Fever Bureau Bulletin, Kala-Azar Bulletin, Journal of Nervous and Mental Diseases, Journal of Comparative Pathology and Therapeutics, British Journal of Dermatology, Journal of the Royal Sanitary Institute, Edinburgh Medical Journal, Journal of the London School of Tropical Medicine, Transvaal Medical Journal, Hospital Assistant (India), South African Medical Record, British Journal of Inebriety, Australian Medical Gazette.

Medical Diary for the ensuing Week.

SOCIETIES.

ROYAL SOCIETY OF MEDICINE, 15, Cavendish-square, W. (temporary address during building of new house).

TUESDAY.

SURGICAL SECTION (Hon. Secretaries—L. A. Dunn, James Berry): at 5.30 P.M.

Debate:

On the Talma-Morison Operation, opened by Mr. Rutherford Morison (Newcastle). The following will take part in the Discussion: Mr. Sampson Handley, Mr. W. G. Spencer, Mr. Waring, Dr. Drummond, Dr. Hale-White, Dr. Rolleston, Dr. Essex Wynter, and others.

FRIDAY.

LARYNGOLOGICAL SECTION (Hon. Secretaries—W. H. Kelson, Dan McKenzie), at 11, Chandos-street, W.: at 4.30 P.M.

Cases

Will be shown by Dr. Wylie, Dr. Kelson, and others.

GENERAL MEETING OF FELLOWS at 4.45 P.M.

Election of Candidates for Fellowship.

CLINICAL SECTION (Hon. Secretaries: James Galloway, Charles H. Fagge): at 8.30 P.M.

Cases:

Dr. F. Parkes Weber: Case of Recurrent Aphasia with High Blood Pressure.

Dr. H. E. Symes-Thompson: Congenital Pulmonary Stenosis in a Woman aged 34.

And other Cases.

Paper:

Dr. H. C. Cameron: The Relative Value of Early and Delayed Operation in Pneumococcal Peritonitis.

MEDICAL SOCIETY OF LONDON, 11, Chandos-street, Cavendish-square, W.

MONDAY.—8.30 P.M., Dr. H. Orton: The X Ray Diagnosis of Pulmonary Disease (illustrated by the epidiascope).

SOCIETY FOR THE STUDY OF INEBRIETY, Rooms of the Medical Society of London, 11, Chandos-street, Cavendish-square, W.

TUESDAY.—3.30 P.M., Council Meeting. 4 P.M., Discussion on Alcoholism and Problems of Growth and Development (opened by Mr. H. Gilford).

UNITED SERVICES MEDICAL SOCIETY, Royal Army Medical College, Grosvenor-road, S.W.

WEDNESDAY.—5 P.M., Lieut.-Col. C. H. Burtchaell, R.A.M.C.: The Army Medical Service with Lord Methuen's Force during the Advance on Kimberley in 1899, with Reference to the Present Organisation of the Medical Service in War.

HUNTERIAN SOCIETY, London Institution, Finsbury-circus, E.C.

WEDNESDAY.—8.30 P.M., Council Meeting. 9 P.M., Mr. C. A. Ballance: The Science and Art of Surgery in Certain Emergencies.

WIMBLEDON AND DISTRICT MEDICAL SOCIETY, Johnston's Rooms, 6, Broadway, Wimbledon.

FRIDAY.—9 P.M., Member's Clinical Evening.

LECTURES, ADDRESSES, DEMONSTRATIONS, &c.

MEDICAL GRADUATES' COLLEGE AND POLYCLINIC, 22, Chenies-street, W.C.

MONDAY.—4 P.M., Dr. J. Galloway: Clinique (Skin). 5.15 P.M. Lecture:—Dr. E. F. Bashford: The Present Aspects of Some Cancer Problems (with lantern demonstration).

TUESDAY.—4 P.M., Dr. J. Taylor: Clinique (Medical). 5.15 P.M., Lecture:—Dr. J. Morrison: Some Difficulties in Labour during the Second Stage.

WEDNESDAY.—4 P.M., Mr. A. H. Tubby: Clinique (Surgical). 5.15 P.M., Lecture:—Mr. J. S. Joly: The Diagnosis and Treatment of Cancer of the Prostate.

THURSDAY.—4 P.M., Mr. P. M. Heath: Clinique (Surgical). 5.15 P.M., Lecture:—Dr. C. O. Hawthorne: Hemianopsia.

FRIDAY.—4 P.M., Mr. K. Campbell: Clinique (Eye).

POST-GRADUATE COLLEGE, West London Hospital, Hammersmith-road, W.

MONDAY.—10.30 A.M., Surgical Registrar: Demonstration of Cases in Wards. Dr. Simson: Diseases of Women. 12 noon, Dr. Bernstein: Pathological Demonstration. 2 P.M., Medical and Surgical Clinics. X Rays. Operations. 2.30 P.M., Mr. Dunn: Diseases of the Eye. 5 P.M., Lecture:—Mr. Bidwell: Treatment of Cancer of the Colon.

TUESDAY.—10 A.M., Dr. Robinson: Gynæcological Operations. 11.30 A.M., Mr. Etherington-Smith: Demonstration of Minor Operations. 2 P.M., Medical and Surgical Clinics. X Rays. Operations. Dr. Davis: Diseases of the Throat, Nose, and Ear. 2.30 P.M., Dr. Abraham: Diseases of the Skin. 5 P.M., Lecture:—Dr. Davis: Diseases of the Ear. (Lecture I.)

WEDNESDAY.—10 A.M., Dr. Saunders: Diseases of Children. Dr. Davis: Operations of the Throat, Nose, and Ear. 10.30 A.M., Surgical Registrar: Demonstration of Cases in Wards. 2 P.M., Medical and Surgical Clinics. X Rays. Operations. Mr. B. Harman: Diseases of the Eye. 2.30 P.M., Dr. Simson: Diseases of Women. 5 P.M., Lecture:—Mr. Ll. Williams: Principles of Treatment of Diseases of Children's Teeth.

THURSDAY.—10 A.M., Dr. Simson: Gynæcological Demonstration. 12.15 P.M., Lecture:—Dr. G. Stewart: Practical Medicine. 2 P.M., Medical and Surgical Clinics. X Rays. Operations. 2.30 P.M., Mr. Dunn: Diseases of the Eye. 5 P.M., Lecture:—Mr. Ll. Williams: Causes of Sepsis of the Mouth.

FRIDAY.—10 A.M., Dr. Robinson: Gynæcological Operations. 2 P.M., Medical and Surgical Clinics. X Rays. Operations. Dr. Davis: Diseases of the Throat, Nose, and Ear. 2.30 P.M., Dr. Abraham: Diseases of the Skin. 5 P.M., Lecture:—Mr. Pritchard: Clinical Pathology.

SATURDAY.—10 A.M., Medical Registrar: Demonstration of Cases in Wards. Dr. Saunders: Diseases of Children. Dr. Davis: Operations of the Throat, Nose, and Ear. Mr. Bishop Harman: Diseases of the Eye. 2 P.M., Medical and Surgical Clinics. X Rays. Operations.

LONDON SCHOOL OF CLINICAL MEDICINE, Dreadnought Hospital, Greenwich.

MONDAY.—2 P.M., Operations. 2.15 P.M., Mr. Turner: Surgery. 3.15 P.M., Sir Dyce Duckworth: Medicine. 4.30 P.M., Mr. R. Lake: Ear and Throat. Out-patient Demonstrations:—10 A.M., Surgical and Medical. 12 noon, Ear and Throat.

TUESDAY.—2 P.M., Operations. 3.15 P.M., Dr. R. Wells: Medicine. 2.15 P.M., Mr. R. Carling: Surgery. 4.15 P.M., Sir M. Morris: Diseases of the Skin. Out-patient Demonstrations:—10 A.M., Surgical and Medical. 12 noon, Skin.

WEDNESDAY.—2 P.M., Operations. 2.15 P.M., Dr. F. Taylor: Medicine. 3.30 P.M., Mr. Cargill: Ophthalmology. Out-patient Demonstrations:—10 A.M., Surgical and Medical. 11 A.M., Eye.

THURSDAY.—2 P.M., Operations. 2.15 P.M., Dr. G. Rankin: Medicine. 3.15 P.M., Sir W. Bennett: Surgery. Out-patient Demonstrations:—10 A.M., Surgical and Medical. 12 noon, Ear and Throat.

FRIDAY.—2 P.M., Operations. 2.15 P.M., Sir J. Rose Bradford: Medicine. 3.15 P.M., Mr. McGavin: Surgery. Out-patient Demonstrations:—10 A.M., Surgical and Medical. 12 noon, Skin.

SATURDAY.—10 A.M., Radiography. 11 A.M., Dr. A. Davies: Pathological Demonstration. 2 P.M., Operations. Out-patient Demonstration:—10 A.M., Surgical and Medical. 11 A.M., Eye.

ROYAL INSTITUTION OF GREAT BRITAIN, Albemarle-street, Piccadilly, W.

TUESDAY.—3 P.M., Dr. P. C. Mitchell: The Childhood of Animals—VI., The Play of Young Animals.

ANCOATS HOSPITAL, Manchester.

THURSDAY.—4.15 P.M., Mr. W. R. Douglas: Chronic Enlargements of the Testicle. (Post-Graduate Clinic.)

OPERATIONS.

METROPOLITAN HOSPITALS.

MONDAY (8th).—London (2 P.M.), St. Bartholomew's (1.30 P.M.), St. Thomas's (3.30 P.M.), St. George's (2 P.M.), St. Mary's (2.30 P.M.), Middlesex (1.30 P.M.), Westminster (2 P.M.), Chelsea (2 P.M.), Samaritan (Gynæcological, by Physicians, 2 P.M.), Soho-square (2 P.M.), Gt. Northern Central (2.30 P.M.), West London (2.30 P.M.), London Throat (9.30 A.M.), Royal Free (2 P.M.), Guy's (1.30 P.M.), Children, Gt. Ormond-street (9 A.M.), St. Mark's (2.30 P.M.), Central London Throat and Ear (Minor 9 A.M., Major 2 P.M.).

TUESDAY (9th).—London (2 P.M.), St. Bartholomew's (1.30 P.M.), St. Thomas's (3.30 P.M.), Guy's (1.30 P.M.), Middlesex (1.30 P.M.), Westminster (2 P.M.), West London, (2.30 P.M.), University College (2 P.M.), St. George's (1 P.M.), St. Mary's (1 P.M.), St. Mark's (2.30 P.M.), Cancer (2 P.M.), Metropolitan (2.30 P.M.), London Throat (9.30 A.M.), Samaritan (9.30 A.M. and 2.30 P.M.), Throat, Golden-square (9.30 A.M.), Soho-square (2 P.M.), Chelsea (2 P.M.), Children, Gt. Ormond-street (9 A.M. and 2 P.M., Ophthalmic, 2 P.M.), Tottenham (2.30 P.M.). Central London Throat and Ear (Minor, 9 A.M., Major, 2 P.M.), Royal National Orthopædic (9.30 A.M. and 4 P.M.).

WEDNESDAY (10th).—St. Bartholomew's (1.30 P.M.), University College (2 P.M.), Royal Free (2 P.M.), Middlesex (1.30 P.M.), Charing Cross (3 P.M.), St. Thomas's 2 P.M.), London (2 P.M.), King's College (2 P.M.), St. George's (Ophthalmic, 1 P.M.), St. Mary's (2 P.M.), St. Peter's (2 P.M.), Samaritan (9.30 A.M. and 2.30 P.M.), Gt. Northern Central (2.30 P.M.), Westminster (2 P.M.), Metropolitan (2.30 P.M.), London Throat (9.30 A.M.), Cancer (2 P.M.), Throat, Golden-square (9.30 A.M.), Guy's (1.30 P.M.), Royal Ear (2 P.M.), Children, Gt. Ormond-street (9 A.M. and 9.30 A.M., Dental, 2 P.M.), Tottenham (Ophthalmic, 2.30 P.M.), West London (2.30 P.M.), Central London Throat and Ear (Minor, 9 A.M., Major, 2 P.M.).

THURSDAY (11th).—St. Bartholomew's (1.30 P.M.), St. Thomas's (3.30 P.M.), University College (2 P.M.), Charing Cross (3 P.M.), St. George's (1 P.M.), London (2 P.M.), King's College (2 P.M.), Middlesex (1.30 P.M.), St. Mary's (2.30 P.M.), Soho-square (2 P.M.), North-West London (2 P.M.), Gt. Northern Central (Gynæcological, 2.30 P.M.), Metropolitan (2.30 P.M.), London Throat (9.30 A.M.), Samaritan (9.30 A.M and 2.30 P.M.), Throat, Golden-square (9.30 A.M.), Guy's (1.30 P.M.), Royal National Orthopædic (9 A.M. and 3.30 P.M.), Royal Ear (2 P.M.), Children Gt. Ormond-street (9 A.M. and 2 P.M.), Tottenham (Gynæcological, 2.30 P.M.), West London (2.30 P.M), Central London Throat and Ear (Minor, 9 A.M., Major, 2 P.M.).

FRIDAY (12th).—London (2 P.M.), St. Bartholomew's (1.30 P.M.), St. Thomas's (3.30 P.M.), Guy's (1.30 P.M.), Middlesex (1.30 P.M.), Charing Cross (3 P.M.), St. George's (1 P.M.), King's College (2 P.M.), St. Mary's (2 P.M.), Ophthalmic (10 A.M.), Cancer (2 P.M.), Chelsea (2 P.M.), Gt. Northern Central (2.30 P.M.), West London (2.30 P.M.), London Throat (9.30 A.M.), Samaritan (9.30 A.M. and 2.30 P.M.), Throat, Golden-square (9.30 A.M.), Royal National Orthopædic (3.30 P.M.), Soho-square (2 P.M.), Children, Gt. Ormond-street (9 A.M., Aural, 2 P.M.), Tottenham (2.30 P.M.), St. Peter's (2 P.M.)., Central London Throat and Ear (Minor, 9 A.M., Major, 2 P.M.).

SATURDAY (13th).—Royal Free (9A.M.), London (2 P.M.), Middlesex (1.30 P.M.), St. Thomas's (2 P.M.), University College (9.15 A.M.), Charing Cross (2 P.M.), St. George's (1 P.M.), St. Mary's (10 A.M.), Throat, Golden-square (9.30 A.M.), Guy's (1.30 P.M.), Children, Gt. Ormond-street (9 A.M. and 9.30 A.M.), West London (2.30 P.M.).

At the Royal Eye Hospital (2 P.M.), the Royal London Ophthalmic (10 A.M.), the Royal Westminster Ophthalmic (1.30 P.M.), and the Central London Ophthalmic (2 P.M.), Hospital operations are performed daily.

EDITORIAL NOTICES.

IT is most important that communications relating to the Editorial business of THE LANCET should be addressed *exclusively* "TO THE EDITOR," and not in any case to any gentleman who may be supposed to be connected with the Editorial staff. It is urgently necessary that attention should be given to this notice.

It is especially requested that early intelligence of local events having a medical interest, or which it is desirable to bring under the notice of the profession, may be sent direct to this office.

Lectures, original articles, and reports should be written on one side of the paper only, AND WHEN ACCOMPANIED BY BLOCKS IT IS REQUESTED THAT THE NAME OF THE AUTHOR, AND IF POSSIBLE OF THE ARTICLE, SHOULD BE WRITTEN ON THE BLOCKS TO FACILITATE IDENTIFICATION.

Letters, whether intended for insertion or for private information, must be authenticated by the names and addresses of their writers—not necessarily for publication.

We cannot prescribe or recommend practitioners.

Local papers containing reports or news paragraphs should be marked and addressed "To the Sub-Editor."

Letters relating to the publication, sale and advertising departments of THE LANCET *should be addressed "To the Manager."*

We cannot undertake to return MSS. not used.

MANAGER'S NOTICES.

THE INDEX TO THE LANCET.

The Index and Title-page to Vol. II. of 1911 were given in THE LANCET of Dec. 30th, 1911.

VOLUMES AND CASES.

VOLUMES for the second half of the year 1911 will be ready shortly. Bound in cloth, gilt lettered, price 16*s.*, carriage extra.

Cases for binding the half-year's numbers are now ready. Cloth, gilt lettered, price 2*s.*, by post 2*s.* 3*d.*

To be obtained on application to the Manager, accompanied by remittance.

TO SUBSCRIBERS.

WILL Subscribers please note that only those subscriptions which are sent direct to the Proprietors of THE LANCET at their Offices, 423, Strand, London, W.C., are dealt with by them? Subscriptions paid to London or to local newsagents (with none of whom have the Proprietors any connexion whatever) do not reach THE LANCET Offices, and consequently inquiries concerning missing copies, &c., should be sent to the Agent to whom the subscription is paid, and *not* to THE LANCET Offices.

Subscribers, by sending their subscriptions direct to THE LANCET Offices, will insure regularity in the despatch of their Journals and an earlier delivery than the majority of Agents are able to effect.

THE COLONIAL AND FOREIGN EDITION (printed on thin paper) is published in time to catch the weekly Friday mails to all parts of the world.

The rates of subscriptions, post free from THE LANCET Offices, have been reduced, and are now as follows:—

FOR THE UNITED KINGDOM.		TO THE COLONIES AND ABROAD.	
One Year	£1 1 0	One Year	£1 5 0
Six Months	0 12 6	Six Months	0 14 0
Three Months	0 6 6	Three Months	0 7 0

(The rate for the United Kingdom will apply also to Medical Subordinates in India whose rates of pay, including allowances, is less than Rs.50 per month.)

Subscriptions (which may commence at any time) are payable in advance. Cheques and Post Office Orders (crossed "London County and Westminster Bank, Covent Garden Branch") should be made payable to the Manager, Mr. CHARLES GOOD, THE LANCET Offices, 423, Strand, London, W.C.

TO COLONIAL AND FOREIGN SUBSCRIBERS.

SUBSCRIBERS ABROAD ARE PARTICULARLY REQUESTED TO NOTE THE RATES OF SUBSCRIPTIONS GIVEN ABOVE.

The Manager will be pleased to forward copies direct from the Offices to places abroad at the above rates, whatever be the weight of any of the copies so supplied.

SOLE AGENTS FOR AMERICA—Messrs. WILLIAM WOOD AND CO., 51, Fifth Avenue, New York, U.S.A.

METEOROLOGICAL READINGS.

Mosse, Berlin; Manchester Royal Infirmary, Secretary of; Manchester Corporation, Clerk to the; Mr. R. Mayman, Milton-under-Wychwood; Marris Products Co., Lond., Manager of; Messrs. Maple and Co., Lond.; Mr. G. E. Mould, Rotherham; Dr. H. W. G. Macleod, Lond.; Mr. J. M. Mangan, Ennis.

N.—Mr. J. C. Needes, Lond.; Mr. H. Needes, Lond.; National Provident Institution, Lond., Secretary of; Newcastle-on-Tyne Hospital for Sick Children, Secretary of; Nottingham General Hospital, Assistant Secretary of; Messrs. Nicholls and Clarkson, Lond.; New Transport Co., Lond., Secretary of; Northampton General Hospital, Secretary of; Mr. S. Nash, Lond.; National Hospital for the Paralysed and Epileptic, Lond., Dean of; Mr. W. Drummond Norie, Los Gatos.

O.—Dr. O. W. Ogden, Newcastle-on-Tyne; Mr. C. D. Outred, Gravesend; Oxford County Asylum, Clerk to the.

P.—Mr. W. R. Paul, Pudukotai; *Le Progrès Médicale*, Paris; Mr. J. Herbert Parsons, Lond.; Mr. H. A. Piper, Lond.; Pneumosan Chemische Fabrik, Lond., Secretary of; Pendyffryn Hall, Penmaenmawr, Secretary of.

Q.—Messrs. Quibell, Bros., Newark.

R.—Royal Society of Arts, Lond.; Dr. R. R. Rentoul, Liverpool; Royal Sanitary Institute, Lond., Secretary of; Royal Institution, Lond.; Royal Hampshire County Hospital, Winchester, Secretary of; Messrs. Richardson and Co., Lond.; Royal Albert Institute' Lancaster, Secretary of; Messrs. J. D. Riedell Co., Lond.; Messrs. Rebman, Lond.; Dr. J. D. Rolleston, Lond.; Registered Nurses Society, Lond., Secretary of; Messrs. George Routledge and Sons, Lond.; Royal Microscopical Society, Lond.; Royal Society of Portrait Painters, Lond.

S.—Dr. W. T. Shananan, Sonyea; Dr. Edmund M. Smith, York; South Yorkshire Asylum, Wadsley, Clerk to the; The Spice Mill Publishing Co., New York, Manager of; St. Andrew's Hospital, Northampton, Secretary of; Dr. H. G. Stacey, Leeds; Messrs. G. Street and Co., Lond.; Mr. J. W. Staniforth, Hinderwell; Showell's Brewery Co., Birmingham; Scholastic, Clerical, &c., Association, Lond.; Smith's Advertising Agency, Lond.; *South Wales Argus*, Newport, Manager of.

T.—Dr. F. G. Thomson, Bath; Mr. L. L. Thain, Ewyas Harold; Taunton and Somerset Hospital, Secretary of; Dr. F. Thorne, Banbury; Dr. H. G. Turney, Lond.; Mr. A. H. Tubby, Lond.; Mr. Reginald Thorpe, Lond.

U.—United Brokerage Co., Chicago, Manager of; United Services Medical Society, Lond.; University College, Lond., Provost of,

V.—Messrs. J. W. Vickers and Co., Lond.

W.—Dr. W. Hale White, Lond.; Mr. Hubert H. B. Wilkinson, Rotherham; Dr. R. J. Warrington, Manchester; Dr. G. Webb, St. Petersburg; Mr. J. Willing, Lond.; Dr. W. D. Wilkins, Rainhill; Weston-super-Mare Hospital, Secretary of; Dr. R. T. Williamson, Manchester; West Ham and Eastern General Hospital, Lond., Secretary of; Warneford, Leamington, and South Warwickshire General Hospital, Secretary of; Dr. Webb, Birmingham; Wolverhampton General Hospital, Secretary of; Mr. Charles Wray, Lond.

Letters, each with enclosure, are also acknowledged from—

A.—Mr. D. Armour, Lond.; Dr. A. B. Atherton, Fredericktown, Canada; Ahmedabad Medical Society, India, Secretary of; Army and Navy Male Nurses' Co-operation, Lond., Secretary of; Dr. A. Ashkenny, Lond.; Dr. G. Atlee, Lond.; Messrs. Allen and Hanburys, Lond.; Apollinaris Co., Lond.

B.—Dr. R. H. Bellwood, Nottingham; Bayer Co., Lond.; Messrs. Burgoyne, Burbidges, and Co., Lond.; British Viavi Co., Lond.; Bloomsbury Dispensary, Lond., Secretary of; Dr. J. Barras, Govan; Messrs. Boyveau and Chevillet, Paris; Messrs. Becker and Wedde, Odessa; Dr. C. Bage, Melbourne; Mr. W. A. Beet, Beaudesert; Mr. T. Bates, Worcester; Messrs. J. Beal and Son, Brighton; Mr. J. J. F. Bourke, Queensland; Mr. G. Billing, Blackpool; Mr. G. M. Braine-Hartnell, Powick; Mr. F. J. F. Barrington, Lond.; Dr. T. W. Buckley, Thrapston; Dr. R. A. Brewis, Dursley; Mr. J. Busfield, Claygate; Mr. J. A. Barth, Leipzig; Dr. J. M. Bennion, St. Mary Cray; Dr. H. P. Byers, Melita, Canada; Blackburn Infirmary, Secretary of; Mr. H. Brown, Caterham; Mr. F. B. Judge Baldwin, Bodicote; Fleet-Surgeon R. F. Bate, R.N., East Liss; Mr. P. Benham, East Grinstead; Birmingham Corporation, Treasurer to the; Mr. J. J. Barry, Fermoy; B., West Ealing; Mr. C. Birchall, Liverpool; Brighton, Hove, and Preston Dispensary, Secretary of; Mr. J. Bolton, Lond.

C.—Mr. W. Chitty, Bristol; Cambridge Hospital Medical Library, Aldershot, Secretary of; Dr. H. W. J. Cook, Shepparton, Australia; C. B. H.; Dr. C. Chaplin, Angmering; Mrs. Caple, Bristol; Messrs. J. and A. Carter, Lond.; Dr. A. R. Carmichael, Liverpool; Dr. E. Cullman, Isleworth; Mr. G. H. Curtis, Ewell; Messrs. E. W. Carling and Co., Lond.; Messrs. Claye and Son, Stockport; Mr. A. Carless, Lond.; Mr. J. J. Culmer, Nassau; County Asylum, Whittingham, Clerk to the; C. G. R. W.; Dr. C. Cochrane, Sellyoak; Dr. J. Campbell, Newbiggen-by-Sea; C. S. E. W.

A Lecture
ON
THE RELATIONSHIP OF TUBERCULOSIS TO ACCIDENT AND INJURY.

Delivered at the Hospital for Consumption and Diseases of the Chest, Brompton,

BY WM. CECIL BOSANQUET, M.D. OXON., F.R.C.P. LOND.,
ASSISTANT PHYSICIAN TO THE HOSPITAL FOR CONSUMPTION AND DISEASES OF THE CHEST, BROMPTON; PHYSICIAN TO OUT-PATIENTS, CHARING CROSS HOSPITAL.

GENTLEMEN,—It is always somewhat difficult to find a suitable subject for a lecture in this course, as there are few themes which seem to present any degree of novelty, most subjects which fall within the limits proper for discussion at this hospital having been exhaustively dealt with by former lecturers or treated of in the excellent text-books of medicine now available. It occurred to me that the question of the relationship of tuberculosis to accidents and injuries is not often so discussed, and though only a small number of the cases in which the question arises are in connexion with the chest, yet these cannot be separated from the rest of the group, and their existence may justify the choice of the subject for treatment in a lecture at this hospital.

It is, indeed, a subject which has assumed very considerable importance in recent years owing to the enactment of legislative measures, such as the Employers' Liability Act and the Workmen's Compensation Act. Actions at law are frequent under these statutes, and it may fall to the lot of any practitioner to have to exercise his judgment as to the alleged causal connexion between an accident and some morbid condition which has followed it. The position of a medical witness is never, perhaps, a particularly enviable one, and it is especially unpleasant when he is called on to testify in regard to matters to which he has previously given little attention, and on which he has therefore formed no very clearly defined opinion.

On this account it may not be unprofitable to consider the theoretical principles which are applicable to such claims as may arise in connexion with tubercular infection. I shall have occasion to refer to one or two cases of this nature which have recently fallen within my own experience and have caused me to realise some of the difficulties which may trouble the medical witness or referee.

Now, the first important point which arises in cases of this kind is to establish the reality of the causal connexion between the accident and the subsequent tuberculosis, and we have to be clear in our minds as to what we mean by a cause. In ordinary speech we talk of cause and effect as if there was usually one cause which was always followed by a definite consequent, but a little consideration shows that the cause of any phenomenon is rather the existence of a group of conditions which unite to produce it, and the absence of any one of which would prevent its appearance.

Thus, in the case of an infective disease there must be first a pathogenic organism and a host capable of harbouring it, and then the germ must be brought into contact with the potential host, and the condition of the latter at the moment must be such as to admit of the growth of the parasite. The patient must be susceptible at the time of the attack, this susceptibility being a variable factor. We know, for example, that of those who are exposed to any infection only a small proportion actually "take" the disease, while a person who has escaped in one epidemic may fall a victim in another.

The important factors, then, which we have to consider in the present connexion are the possibility (1) that an accident or other injury may be the means by which tubercle bacilli are introduced into a person; or (2) that the injury may cause a weakening of natural resistance to the bacillus and thus permit it to establish itself when it would not otherwise have done so, or may lead to dissemination of the bacilli, thus giving rise either to a new focus of tuberculosis or to extension of one already existing.

Now there are certain peculiarities about the tubercle bacillus whereby the disorder resulting from its growth in the human body is distinguished from most other infective diseases. These characters tend to render the problem of the relationship between an injury and the subsequent tubercular infection specially difficult to determine.

1. In the first place, the organism is fairly ubiquitous, so that most, if not all, persons are brought into contact with it in the course of their lives. German writers have maintained that by middle life every one has been infected, the bodies of all persons who have reached or passed that period of life showing, if carefully examined, some deposit of tubercle. In the majority of instances no sign of the disease was ever manifested during life, but the existence of the healed lesions shows that the bacilli did at one time actually establish a footing and produce local disturbance.

And we know that in such lesions, even when they are apparently obsolete or quiescent, there are usually present living organisms which may set up further disease, either by direct spread in the neighbourhood or by carriage to distant parts, if the resistance of the individual is sufficiently reduced. A familiar instance of this spread from an old focus is seen in the acute general tuberculosis of young children, in whom we can almost always find a caseating gland from which the overwhelming dose of bacilli has been thrown into the circulation and led to the generalised affection. We cannot always trace the exact factors which thus lower the resistance, and the resulting attacks are apparently spontaneous; so that if we do not make a necropsy and thus discover the old quiescent lesion, we may even suppose that a fresh infection has occurred from without.

If, then, so many persons have quiescent foci of tuberculosis within them, and if we cannot usually determine exactly what has depressed the resistance and led to spread of infection in ordinary cases, it is clear that it must always be problematical whether any particular accident has been the cause at work. The outbreak may have been an accidental sequel, not a consequence of the injury.

2. Secondly, we have to recognise that the tubercle bacillus is a slowly growing organism in the majority of instances, so that symptoms of disease do not arise until some considerable period of time has elapsed after its actual introduction into the body or its establishment in some new focus. Contrast it, for example, with the infection of erysipelas, in which severe symptoms will probably develop within a few days of the introduction of the germ, or even with tetanus, in which a fortnight or three weeks may elapse. In the case of tuberculosis months may pass after an injury has occurred before any sign of disease is recognisable. Even when such do appear they may not be at first acute or striking.

It will be most convenient to consider under the different classes of cases the evidence on which we have to rely to establish a connexion between a distant accident and subsequent tuberculosis. We may consider first those instances in which the tubercular infection results directly from the injury, and afterwards those in which the latter produces some weakening of resistance or other disturbance in a person in whom tubercle bacilli are already present, and thus leads to extension of the disease.

I.—DIRECT INFECTION WITH TUBERCLE BACILLI.

This may result from injuries caused by instruments to which the bacilli are adherent, or from subsequent infection of an open wound by contact with infected objects.

Of the former type the best-known example is the often-quoted case of the nurse who cut herself with a fragment of a broken spittoon which had contained tuberculous sputum (Tschering). Similarly, in the process of tattooing, a tuberculous operator has inoculated the disease, either by moistening the skin with saliva, or owing to the needle being contaminated by being held in his mouth when out of use. As is well known, syphilis has been conveyed in the same way. Letulle records a case in which a woman, while scrubbing the floor of a room in which her husband had recently died from tuberculosis of the lungs, ran a splinter of wood from one of the boards into her hand; the wound subsequently became the seat of tuberculosis. A bite from a tuberculous husband is said to have caused the appearance of local tuberculosis of the lip (B. Schmidt).

Butchers and veterinary surgeons are liable to inoculation in the course of their work in cutting up infected cattle. Thus Pfeiffer describes the case of a veterinary surgeon who cut his thumb in dissecting a cow; tuberculosis of one of the

articulations followed, and ultimately tuberculosis of the lungs. Pathologists may suffer similarly in making human necropsies, and in days before the wearing of indiarubber gloves was as general as it now is, it was not uncommon for them to be affected with the condition known as "anatomical tubercle," or tubercula necrogenica, a form of slowly developing verrucose tuberculosis of the skin arising either from inoculation of slight cuts or scratches, or from the entry of the bacilli through sweat-ducts or hair-follicles.

Infection of existing wounds by bacilli may also occur, as in the case of a laundress who suffered from a whitlow. This was infected with tuberculosis in the course of her occupation, through washing the linen of a tuberculous patient. A consumptive mohel, or ritual operator, has been known to spread infection in the performance of circumcision, either by applying his mouth to the wound to stop bleeding or by squirting a mouthful of wine over the cut surface as part of the procedure.

It is often difficult to distinguish between the two classes of cases just considered, as we do not know if the object causing the injury was itself contaminated. Thus, in one recorded case, in which a butcher's assistant fell and cut his elbow, the wound subsequently becoming the seat of tuberculosis, it may have been that the bacilli were inoculated directly at the time of the accident, being present on the portion of ground with which he came into contact, or the wound may have been subsequently infected in the course of his occupation (Wichmann).

Before leaving the present group we may note the sequence of events. There is first a wound or abrasion. The resulting tuberculosis may be limited to the skin, taking the form of lupus or verrucose tubercle; or the trouble may spread deeper. In the latter event its natural course is by the lymphatics, which become the seat of tubercular lymphangitis, and the lymphatic glands to which they lead become involved. The intervening lymphatics may appear to escape, as in a case quoted by Niché, in which a man cut his hand in undoing a bundle of straw. Subsequently a swelling appeared in the corresponding axilla, which was refractory to treatment, and had to be removed by operation. It was found to be tuberculous. Other glands became affected and were removed, and finally recovery resulted.

Involvement of neighbouring bones and joints seems to be not uncommon. Thus a man infected his hand in cutting up tuberculous meat, and subsequently suffered from tuberculosis of one of the carpal bones (Rudolph). Even so distant a part as the lungs may ultimately suffer, as in Pfeiffer's case already referred to. A similar sequence following a post-mortem wound is narrated by Letulle; here glandular infection, instead of disease of a joint, preceded the lesion in the lungs.

In another instance a man, aged 30, bruised his foot with a stone which fell on it. The ankle-joint swelled first, then tuberculosis of the skin ensued, followed by tuberculosis of the bones of the foot (which was amputated), and finally by pulmonary tubercle (Feilchenfeld). It seems probable that tuberculosis of the skin implies an infection from without, so that this may have actually been a case of direct inoculation or subsequent infection; but the phenomena closely resembled those seen in the next class of cases with which we shall have to deal.

In the accounts given of the cases referred to no difficulty seems to have been experienced in tracing the connexion between the injury and the subsequent tuberculosis. Symptoms of infection occurred within a few weeks of the occurrence, and the anatomical relationship of the glands or bones affected to the site of injury was fairly close, while in the case of the skin the identity of the seat of the lesions was apparently obvious. So far as the skin is concerned, there will probably be a visible scar remaining, and the cutaneous affection may be readily shown to be connected with this. The original wound may sometimes refuse to heal, or it may seem to heal and then break down again, as in Kluge's experience. This surgeon cut his hand at a necropsy, and the wound healed up; it broke down again ten weeks later as the result of hard riding in the course of his military duties, becoming the seat of tubercular disease; and a condition of tubercular teno-synovitis persisted for some time.

It is worth noting that the term "accident" is apparently given a somewhat wide meaning by courts of law. Hence claims may arise in connexion with any infection arising out of a person's employment. To discuss such subjects as grinder's tuberculosis connected with the inhalation of dust and of tubercle bacilli at their work, or the liability of laundresses to contract the disease from contact with the linen of infected persons, would lead us too far afield. Experience at this hospital certainly points to laundresses as being frequently subject to consumption, but this is probably due to the conditions under which they work rather than to direct infection from the clothes washed.

II.—Extension of Existing Tuberculosis owing to Weakened Resistance or Dissemination of Bacilli.

Under this heading we have to consider all cases in which the bacilli are present in the patient at the time of the accident, which leads either to a local extension of the affection or to its appearance at some distant part of the body. We may also include for convenience those cases in which some new symptom is induced, even apart from ascertainable spread of the tubercular deposit.

If we consider first the pathology of the matter we recognise that a local focus of tuberculosis consists in a mass of inflammatory tissue, the centre of which is probably caseous and soft, living bacilli existing both in the tissues and in the central puriform material. The commonest places for such localised deposits are the lymphatic glands and the lungs. If only deeply seated glands are affected there may be no signs of the disease discoverable, and the person will very probably pass as sound even on careful medical examination. When the lung is involved close scrutiny will usually reveal some alteration of the normal conditions, but not necessarily enough to make diagnosis at all certain.

When the focus of disease is quiescent it is probable that the bacilli remain imprisoned in the inflammatory mass; but whenever it is active, it is at least probable that some of them from time to time escape into the circulation. In the case of pulmonary tuberculosis many observers have carried out systematic examinations of the blood to ascertain whether tubercle bacilli could be found in it. The results obtained have been divergent, some observers finding them only rarely in the circulation, others noting their presence almost invariably. We may conclude that they are at all events frequently "at large." The same is probably true in the case of local tuberculosis of other organs. Hence a source of potential infection is present in many persons, and we can realise how the occurrence of a focus of diminished resistance might admit of the parasites effecting a new settlement in some distant part.

Again, an injury may result in a tearing of the tissues forming the focus of disease, and so may directly cause a liberation of bacilli into the circulation. Thus curettage of a tubercular area may cause an outbreak of miliary tuberculosis, and rough manipulation of a diseased joint may similarly cause an extension of the disease. The extension may be confined to the parts surrounding the original focus or may involve distant organs. A symptom arising from this tearing of the tissues—or from increased strain thrown on the blood-vessels with consequent rupture—which is very common in pulmonary cases, is, of course, the onset of hæmoptysis.

These considerations are fairly simple and straightforward, but the question of the mode in which a local injury predisposes the part affected to become the seat of tuberculosis—depresses its resistance to the germ—is not easily solved. The class of tubercular trouble most often assigned to preceding injury is chronic tuberculosis of joints (white swelling). Now it is generally admitted that severe injuries, such as dislocations, are not often followed by tuberculosis of this nature. The causal condition is some comparatively trivial accident, such as twist or sprain.

We must bear in mind that among certain classes there is always a tendency to find an origin for disease in some antecedent accident, and among them slight injuries are so common that one can usually be found to which any trouble can be attributed. Hence there is room for some scepticism as to reality of the cause assigned in many of such cases. Nevertheless, the balance of opinion seems at present to accept the truth of this mode of causation, and it is supported by evidence of weight. For example, the authorities of the French War Office find that the majority of cases in their army in which amputation of the foot has to be carried out for tubercular disease are attributable to old sprains (*foulures*), and in the case of soldiers the occurrence of the accidents will probably be actually on record and

readily verifiable. This consensus of opinion is reflected by most authors of surgical textbooks and articles, who generally admit this mode of causation, though they differ as to the percentage of cases in which it is found.

Now the pathology of a sprain may be supposed to consist in stretching of ligaments, with rupture of some of their fibres and possible rupture of blood-vessels and extravasation into the joint, followed by reactive hyperæmia, exudation, and multiplication of connective cells, resulting finally in repair. The phenomena accompanying a dislocation are presumably the same, with the trifling exception that the bones forming the joint are displaced from their normal apposition. It is, therefore, not clear why the slighter injury should be followed by tuberculosis and not the more severe. The explanation given—that in the latter case the inflammatory reaction is greater and that the bacilli are prevented from settling by the more thorough flushing with inflammatory fluids—seems inadequate, as the process must go through different degrees of severity in its course towards recovery. Probably the explanation is that tuberculosis only follows injury in a small proportion of all cases, and slight injuries are common, whereas grave lesions are rare; hence the rarity of instances in which it is attributed to grave accidents.

Again, it is remarkable that these cases of tubercular disease of joints arising after injuries occur as a rule in persons who are not obviously the subjects of an existing tuberculosis elsewhere, whereas injuries in consumptive persons do not usually, so far as I am aware, become the seats of tuberculosis, though Feilchenfeld records the case of a man, aged 35, a consumptive, who sprained his wrist and subsequently suffered from tubercular disease of this joint.

The attempt to throw light on the problem by experiments on animals has not led to any very definite results. Thus, early experimenters found that it was possible, by injuring a joint and then injecting tuberculous material into the circulation, to produce an arthritis; but Lannelongue and Achard showed that the inflammation of the joint was due in these cases to other germs than the tubercle bacillus, the condition being septic rather than tubercular. Some experiments of Petrow with pure cultures have, however, established the possibility of a true tuberculosis resulting under these conditions, but the doses of bacilli used were very large compared with anything likely to be present in ordinary conditions of disease. Recently Moultanovsky has found that tuberculosis can be similarly induced in the muscles of rabbits—a tissue not naturally susceptible to this form of infection—by bruising them and then injecting the bacilli into a vein of the ear.

On the other hand, Petrow noted that in tuberculous animals bacilli might be found in the epiphyses and joints, even when no signs of disease were discoverable there, and suggested that an injury may rather light up a smouldering infection than lead to a settlement of circulating organisms there. That this is the case in some instances of human disease seems undoubted, as Lannelongue found that careful inquiry into the past history of some of these patients revealed that there had been pain or swelling of the joint before the accident; and X-ray examination or post-mortem inspection has in other cases proved the existence of old disease.

So far as the question of compensation for accident is concerned it is probably immaterial whether the injury has led to a deposit of tubercle in a part or has merely quickened a latent infection: it is equally a cause of the condition leading to the worker's incapacity. But from the point of view of pathology, there seems much in favour of adopting this last view of the causation of traumatic tubercular arthritis.

It is not necessary for our present purpose to quote a series of cases of articular disease following accidents, as the condition is well recognised and is dealt with in the text-books. It is only needful to point out that there is often a considerable interval between the accident and the appearance of the graver disease; and that the interval may either be quite free from trouble of any kind, or some pain and limitation of movement may persist. The following case of spinal tuberculosis may illustrate the sequence of events after an inquiry.

A middle-aged man was carrying a heavy parcel in each hand and fell in descending an iron staircase. He struck his back in so doing, but was able to continue his work for some weeks, the pain due to the local bruising of the skin and muscles of the back gradually passing off. About six weeks after the accident he noticed a return of pain, and this at times radiated into the legs. Then weakness of the legs gradually ensued, and he came into hospital for this condition. On examination he was found to have weakness and wasting of the muscles of the lower limbs, and an examination with the X rays showed that the upper lumbar vertebræ were disorganised. There were râles in the chest over the upper parts of both lungs and irregular fever of remittent type; but a single examination of the sputum did not reveal the presence of tubercle bacilli. The man developed signs of consolidation of the lower lobe of the right lung with increased fever and weakness, and died in the course of a few days.

No necropsy could be obtained, but there seems little doubt, in spite of the one negative search for tubercle bacilli, that he was suffering from pulmonary tuberculosis, which had existed before the accident, and that as the result of the latter he had developed Pott's disease of the lumbar vertebræ. The strain suffered by the vertebral column had either afforded a spot of weakened resistance to the bacilli circulating in the blood or had awakened to life a quiescent focus of tuberculosis previously seated in the spinal column.

Instances of tuberculosis of the lungs following injury to the chest have been recorded. Thus a mason fell and fractured his skull. He was trephined and recovered from the injury, examination of his chest revealing at this time no disease. During convalescence he developed pain in the side and signs of consolidation of the lung, the condition proving to be tubercular (Thiem). In another case, a man was struck in the side by a heavy box, the injury causing pain in the side in breathing and slight dulness on percussion. Six months later he suffered from hæmoptysis and was found to have tubercular disease (Thiem). In neither of these cases, perhaps, is it absolutely clear that the tuberculosis was produced by the injury.

Jaccoud records the case of a man who received a violent blow in the side, followed by pneumonia. He seemed to recover from this, but some dulness and râles persisted in the affected area. No tubercle bacilli could be found in the sputum. Nineteen months later he developed definite signs of tuberculosis and bacilli were found. The condition terminated fatally, and at the necropsy the appearances suggested that a primary pneumonia had "become tuberculous."

Perhaps the most striking case is that recorded by Schrader. A man, previously healthy, fell from a cart and was rendered unconscious. He attempted to do his work next day, but felt so ill that he had to give up and went into hospital. Here he was found to have severe bruising over the region of the right shoulder, and signs of pneumonia developed in the upper part of the right lung. Ultimately the whole right lung became affected; no fluid was found on puncture of the pleural cavity. The sputum "showed nothing abnormal." Fever of a remittent type continued, and about five weeks after the original accident tubercle bacilli were found in the sputum. The signs gradually abated and recovery finally ensued.

It may be remarked that it is not definitely stated that a search for tubercle bacilli was made when the sputum was first examined, and that even if it were, a single negative examination is not conclusive; so that the possibility remains that the condition was tubercular throughout. It may have been a case in which an accident awakened an existing lesion into activity. Still the connexion of the injury with the subsequent disease is manifest.

The pathology of these pulmonary cases is not very clear. It is suggested that a pneumonia may result from an accident, and that this may "become tubercular." Schrader states that such a sequence is well recognised, but so far as my own experience goes it must be very rare for an ordinary croupous pneumonia to act as a starting point of tuberculosis. A condition of bruising with hæmorrhage in the pulmonary tissues might give rise to similar physical signs, and might, perhaps, provide a suitable soil for the bacilli, if it be true, as has been stated, that miliary tubercles are found in the tissues around extravasations of blood. We must, however, bear in mind the possibility that in these cases there may have been latent tuberculosis of the lung before the accident, and that this was quickened into fresh activity by the lesion.

Another sequence that may be met with is the appearance of pleurisy, with or without effusion, as the result of an injury; signs of tubercular affection of the underlying lung

may subsequently appear. It is even stated that injury to one part of the chest wall may result in tuberculosis of a distant part of the lung, but I think that one would be justified in regarding such an occurrence with considerable scepticism and demanding rather stringent proof of the causal relationship.

With regard to this group of cases, if we are called upon to express an opinion as to the probability of a tubercular lesion being due to a preceding accident, I think we must put disease of joints in a class by itself. There is a considerable mass of evidence, as was noted above, that in some way or other injury does lead to tubercular arthritis; and if the occurrence of the accident is clearly established, and it is followed at a reasonable interval by the tuberculosis, we may accept the causal connexion as probable. As to what constitutes a reasonable period of time, opinions may differ, but it seems unlikely that symptoms would be delayed for more than three months. Also we must look for some sign that recovery has never been perfect—some persistence of pain or stiffness in the joint in the interval. If such have been noted we are almost entitled to speak with that degree of certitude which is beloved by courts of law and sometimes assumed even in matters of opinion by so-called expert witnesses.

On the other hand, if the onset of a case of pulmonary disease were attributed to an injury, we should be obliged to regard the assumption with grave doubt, since the sequence is undoubtedly rare and its very existence may be doubted. To justify such a claim it would be necessary to establish the fact of a grave injury to the chest in the first instance and the probability that the patient was previously sound; and proof must be given that the tubercular lesion has developed at the seat of injury and that some signs of disease have been constantly present there since.

AGGRAVATION OF EXISTING DISEASE.

That injury may cause aggravation of an existing tubercular condition is well established and easily intelligible. Such a result may occur in any part of the body, and the three following examples, taken from Feilchenfeld, may serve as illustrations.

An officer in jumping (on a horse) injured his sacrum and died shortly afterwards with acute generalised tuberculosis. At the necropsy there was found old sacro-iliac disease from which the general infection had spread.

A man slipped and fell, striking his abdomen. He died with symptoms of acute peritoneal trouble, and after death it was found that the mesentery was the seat of old disease and that there was extension of miliary tubercles to the rest of the peritoneum.

A man suffering from consumption fell and broke some ribs. This accident was followed by pleurisy and by aggravation of the disease in the lungs.

In considering questions arising out of cases of this nature we must note that it is only when the injury affects the tuberculous part directly that we can admit without scruple that subsequent increase of the disease is due to it. Much more difficult are cases in which a claim arises that a distant injury has aggravated the existing disease. That it may do so is probable on general grounds, as it is admitted that intercurrent disease—e.g., influenza or erysipelas—may excite the infection to greater activity, and it is reasonable to suppose that an accident may depress the sufferer's resistance. Thus, I have seen a case of acute pneumonia following a motor-car accident, in which the shock and subsequent confinement to bed were apparently predisposing causes of the malady. The same sequence might conceivably lead to aggravation of an existing tuberculosis, but it must be admitted that ascertainable instances of such a sequence are not easy to find.

Feilchenfeld, from whom I have already borrowed so many illustrative cases, records an instance in which a consumptive man was run over by a train, the accident necessitating amputation of the leg. This was followed by prolonged suppuration, and the pulmonary condition was aggravated and death accelerated by the weakening effects of the pyogenic trouble. This case is, however, rather one in which an intercurrent infection was the cause of lowered resistance to the tubercular attack. The mechanism of its action is intelligible in the light of the known phenomena of immunity, which depends on the supply of various chemical bodies, such as bacteriolysins, opsonins, and so forth, so that if the resources of the patient are used up in combating one form of infective agent there will be less available to resist a second.

Of the conditions subsisting in those suffering from the shock and neurasthenia which may follow an accident we know very little, and therefore we have no valid theoretical basis to support any suggestion that such a result of an injury has acted prejudicially on a pre-existing tuberculosis. Still more doubt would arise if it were claimed that an injury and its resultant shock had so depressed a healthy person's resistance that he subsequently fell a victim to tuberculosis of the lungs or elsewhere. I do not know of any instance in which such a claim has been preferred, and I think it would be very difficult to substantiate, but it is well to bear in mind the possibility of such a suggestion.

Before it could be admitted that an accident had aggravated an existing focus of tuberculosis situated at a distance from the part affected by the injury, it would in any case be necessary to show that it was of such gravity as to produce a clear deterioration of general health. Nevertheless, frivolous claims may be formulated in this connexion. Thus, a man came to this hospital suffering from pulmonary tuberculosis and attended for some three months. He then ceased to come and resumed his occupation in a dairy. While at work he scalded his leg, the burn being of the first and second degrees, and involving an area of about the size of the hand. It was treated and healed normally. He came again for treatment for his chest condition, but said nothing of the accident, clearly attributing no importance to it; but after his death, which ensued very shortly, a claim was made by his widow that the accident had accelerated his decease. The case came into court, but the plaintiff did not put in an appearance, the claim being obviously indefensible.

HÆMOPTYSIS.

Lastly, we may refer to the occurrence of hæmorrhage as a result of strain or injury, as it is a common subject of questions. The simplest type of case may be seen in that of a youth aged 18, who came to this hospital saying that he had been lifting a weight, when he was suddenly seized with hæmoptysis. This did not recur, and he stated that he was none the worse for it. Examination revealed tuberculosis at the apices of both lungs, which had evidently been present before the accident.

In a second case a middle-aged man was violently bent backwards by the weight of a heavy ladder thrown on to his arms. He felt pain in the chest for 15 or 20 minutes afterwards, but continued his work. Next day he felt ill, and in the evening was sick and giddy and brought up a small amount of blood; he stated that he vomited and did not cough it up. This recurred several times during the night and the next two days. Since the accident he had been short of breath and had suffered from cough. On examination about a month after the accident there were signs of chronic tuberculosis at the apex of the left lung. He improved markedly under treatment in this hospital, where he came under the care of my colleague, Dr. A. J. Jex-Blake.

Reports of cases of this nature could easily be multiplied if time permitted. The first question generally asked with regard to them is whether the tuberculosis was present before the accident. Now, in any case of hæmoptysis the presumption is that the hæmorrhage is a symptom of previously existing disease. We do not now believe in hæmoptysis giving rise to phthisis (phthisis ab hæmoptoe) as was taught by our forefathers in medicine. It is not impossible that a strain might lead to rupture of a pulmonary vessel apart from tubercular infection, but such a bleeding would not be followed by phthisis. We can be practically sure that if signs of consumption appear soon after an attack of hæmoptysis, there was latent disease present before the occurrence.

We must, however, be prepared to support our views on this point by evidence derived from the signs in the chest and the pathology of the disease. I have not time to deal with this question at length, but it is clear in the first place than an extensive distribution of the physical signs usually implies disease of some duration—e.g., if both apices are affected. In the comparatively rare cases in which a large portion of lung is rapidly involved in an acute tubercular process, the general state of the patient—fever, weakness, and so forth—will readily elucidate the acute nature of the condition. Coarse râles generally point to chronic trouble,

as contrasted with the fine crackles heard over a patch of recent consolidation. Thickening of the pleura also points to long-standing disease.

A more difficult question is that of the effect of the accident on the patient's general health—whether it has aggravated the tuberculosis of the lung as well as causing the hæmorrhage. Of the two cases I have quoted, in the first no such ill-effect seemed to have ensued, and the result of the accident was only to stop the lad from working till the bleeding point had safely closed up.

In the second instance above, there seemed to have been some aggravation of the disease, as the patient who had previously thought himself quite well became weak and short of breath. He rapidly improved, however, and the still more insoluble problem arose at a subsequent period, as to whether he had then recovered from the effects of the accident. It was clearly impossible to disentagle with any certainty the effects of the original disease from those of the slight exacerbation produced by the strain. It seemed, however, reasonable to believe that if improvement occurred the effects of the recent acute process produced by the accident would subside before the effects of the chronic lesion, and after a lapse of about three months, when I re-examined the patient, I came to the conclusion that he was suffering from his original malady and had recovered from the accident.

I hope I have said enough in this brief sketch of the subject to indicate the nature of the problems involved in any study of the relations of tuberculosis to injury and accidents, and to show the importance of such study in view of the social arrangements of our own time.

Researches INTO SENSORY DISTURBANCES FROM CEREBRAL LESIONS.

By HENRY HEAD, M.D. CANTAB., F.R.S.,
PHYSICIAN TO THE LONDON HOSPITAL;
AND
GORDON HOLMES, M.D. DUB.,
ASSISTANT PHYSICIAN TO THE NATIONAL HOSPITAL, QUEEN-SQUARE, AND TO THE SEAMEN'S HOSPITAL, GREENWICH.

(Continued from p. 4.)

II.—SENSORY DISTURBANCES ASSOCIATED WITH CERTAIN LESIONS OF THE OPTIC THALAMUS.

1.—INTRODUCTION.

THROUGHOUT this work it has been our aim to discover the nature of the abnormal sensations evoked by disturbances at different levels of the nervous system. So far our task has been a comparatively easy one on account of the certainty with which the level of the lesion could be determined even in life.

We know that all afferent fibres passing upwards from the mid-brain end in the optic thalamus. Here lie the synaptic junctions of those paths by which impulses are carried onwards to the cortex; no path passes upwards without undergoing a relay in some part of this organ. We shall now attempt to discover the changes in the grouping of afferent impulses which occur after they have terminated in the optic thalamus, and the part played by this organ in sensation.

It is obvious that if all afferent impulses undergo a relay in the optic thalamus, a lesion at a point where they enter this organ may interrupt them before they have undergone re-grouping: they may be cut off before they have reached the thalamic junction, and the loss of sensation would then correspond to that produced by a lesion of the mid-brain, although the disease might lie in the optic thalamus. On the other hand, sensory impulses may reach the optic thalamus undisturbed and undergo characteristic changes in grouping; but the fibres which conduct them from the thalamus to the cortex may be interrupted by the lesion. Finally, since lesions of the optic thalamus are usually of vascular origin and tend to disturb anatomical areas rather than functional paths, they not infrequently interfere both with the impulses which enter the thalamus and with those which pass away from this organ to the cortex.

Our business is to determine the nature of the sensory changes produced by interruption of sensory impulses at various points in their course, and for this purpose we must be able to recognise that a lesion is situated within the optic thalamus. This we can do largely owing to the work of Dejerine and his pupils; for he pointed out, first with Egger [6*] and later with Roussy [7], that lesions which involve the optic thalamus are often characterised by a group of symptoms of which pain in the affected half of the body and other sensory disturbances form an integral part. These clinical symptoms and signs have been further elaborated by Roussy [33], and have been erected by him into a "*syndrome thalamique.*" He has shown that a lesion of the optic thalamus may produce the following characteristic changes:—1. A persistent loss of superficial sensation of one-half of the body and face. This loss to touch, pain, and temperature is more or less definite, but the loss of "deep" sensibility is always more pronounced. 2. Slight hemiataxy and a more or less complete astereognosis. 3. Acute pains on the same side, persistent, paroxysmal, often intolerable, and yielding to no analgesic treatment. 4. Slight hemiplegia which produces no contracture and rapidly passes away. 5. Choreic and athetotic movements in the limbs of the affected side. He pointed out that the sensory loss and the pains are alone due to the lesion of the optic thalamus, whilst the other symptoms are produced by destruction of surrounding parts.

Roussy has now established the anatomical significance of this "*syndrome thalamique*" by five post-mortem examinations. Others have been reported which show the truth of Dejerine's original generalisation.

We ourselves have observed 24 more or less similar cases, with sufficient symptoms and signs to justify us in diagnosing a lesion in the optic thalamus, such as Roussy has described.

The loss of sensation differs in no way from that produced by interference with sensory impulses, either as they enter the optic thalamus or as they pass to the cortex by way of the internal capsule. But to these familiar defects another factor may be added when the lesion destroys certain parts of the optic thalamus. This fresh factor, which alone can be attributed to the disturbed activity of this organ, is a tendency to react excessively to unpleasant stimuli. The prick of a pin, painful pressure, excessive heat or cold, all produce more distress than on the normal half of the body, and this is the essential feature in all the cases with which we shall now deal. There are other cases where the optic thalamus is destroyed in which the spontaneous pains and the characteristic over-response may be absent; but with these we are not concerned at present.

2.—THE EXCESSIVE RESPONSE TO AFFECTIVE STIMULI AND THE BEHAVIOUR IN STATES OF EMOTION OF THE ABNORMAL HALF OF THE BODY.

A.—*The Response to Unpleasant Stimuli.*

(*a*) *To Prick.*

After quoting a case (Case 5) as a characteristic instance of the "*syndrome thalamique*" described by Roussy, the lecturers continued:—

We shall now proceed to investigate the patient's behaviour to measured painful stimuli. If a pin is lightly dragged across her face or trunk from the right to the left half she exhibits intense discomfort when it passes the middle line; she not only calls out that it hurts her more but her face becomes contorted with pain. But she insists that although the stimulus is more painful, it is "less plain" and "less sharp" than over normal parts; the prick is less distinct but it hurts her more.

This "hyperalgesia" or over-reaction would seem to point to a lowered threshold to the prick of a pin. But measured stimulation with both the spring and the weight algesimeters shows that, if anything, the threshold is a little raised. She never responds with certainty over the abnormal (left) half of the body to a stimulus which evokes a sensation of pricking on similar normal parts to the right of the middle line.

* These and other reference numbers relate to a bibliography to appear at the end.

Moreover, if a measured stimulus of the same strength is applied to similar parts more pain is evoked over the affected than over the normal half of the body; the same stimulus, provided it is sufficiently strong to cause pain, produces a more uncomfortable sensation on the abnormal side.

This remarkable over-response to prick was present in 20 out of 22 cases in which the strength of the stimulus was carefully measured. But in no instance was the threshold lower on the affected half of the body; in 13 cases it was identical on the two sides, and in 9 a decidedly stronger stimulus was necessary to produce a sensation of prick in spite of the greater discomfort experienced by the patient when pain had once been evoked.

(*b*) *Painful Pressure.*

Throughout our work we have attempted in every case to measure the amount of pressure which evoked pain. Cattell's algometer was applied to similar parts on the two halves of the body, and the point was registered at which the pressure became uncomfortable.

Now in the class of case with which we are concerned here, pressure is peculiarly liable to produce greater distress and an increased reaction on the affected side. Out of 24 patients every one responded more violently to painful pressure, and all complained that the same pressure, if it evoked discomfort, was more disagreeable on the abnormal than on the normal half of the body.

Moreover, this pain did not develop gradually out of the painless sensation of pressure as on the normal side, but seemed, over the affected parts, to appear explosively. Up to a certain point the patient remained unconcerned, but suddenly, as the pressure increased, he would cry out and withdraw the limb to which the instrument was applied; from the expression of his face he had obviously been more hurt than by the same pressure on the equivalent normal part.

This increased reaction is frequently, though not necessarily, associated with the lowering of the threshold; the same pressure may be required on both sides to evoke pain, although the response on the affected half of the body is excessive (6 cases). In 3 cases, including one which came to post-mortem examination, the threshold was actually higher on the side of the greater reaction.

Although this increased reaction may occur with a normal and even with a raised threshold, we found that in 15 out of our 24 cases the pressure necessary to cause discomfort was less on the affected side. This was particularly the case on the palm and sole of the foot. But in spite of this lowering of the threshold to painful pressure, not one of these cases showed a lower threshold when the stimulus was a prick. Obviously the pain produced by excessive pressure contains some sensory factor to which the abnormal half of the body is peculiarly susceptible.

Now if anyone will apply the algometer to his own hand or foot he will find that the pressure causes discomfort rather than pain. There is something terrifying about the crushing sensation, especially when a bone is pressed upon. The condition evoked is less a pain than an unbearable and distressing sensation, and in this way differs profoundly from the prick of a sharp point. Both stimuli produce pain and discomfort; but whereas a prick produces a sensation of pain associated with more or less discomfort, pressure upon bones and other deep structures evokes more discomfort than formal pain.

In these cases of over-reaction on the affected half of the body it is susceptibility to the uncomfortable element of a stimulus which is increased rather than sensibility to pain. Not uncommonly the threshold may be actually raised to prick but lowered to pressure-pain, although both stimuli produce greatly increased discomfort over abnormal parts.

Any loss of sensibility to pain delays the appearance of this over-reaction, but as soon as the stimulus is strong enough to cause pain the discomfort will greatly exceed that produced by the same strength of stimulus over normal parts.

(*c*) *Extremes of Heat and Cold.*

Wherever this over-reaction to painful stimuli exists the response to the more extreme degrees of heat and cold is changed. Thermal appreciation may be unaltered, may be diminished, or may be actually lost, and yet the discomfort produced by cold and hot water will be greater on the affected than on the normal half of the body.

All sensibility to heat and cold may be lost, and yet this over-reaction may still occur on the affected side. But in such cases the stimulus must be intense; the heat applied must be above 50° C., and the cold required will usually lie below 15° C, and sometimes even melting ice is necessary to evoke this over-reaction. But when once a stimulus has been found capable of producing a response, the discomfort is excessive on the affected half of the body.

To the most interesting group, however, belong those cases where an excessive response was evoked on the affected side in spite of a thermal sensibility otherwise perfect. In one case, for instance, the threshold for the appreciation of heat and cold was identical on the two halves of the body. But whenever a stimulus produced any but the mildest sensation of cold it seemed "colder" and more unpleasant over the affected than over the normal palm. A stimulus recognised as warm did not become "hotter" on the affected hand until it was raised to between 40° and 45° C.

Thus, in conclusion, whenever a thermal stimulus can produce discomfort this will be greater on the affected than on the normal side. Should the appreciation of heat and cold be sufficiently preserved this discomfort will be thought to imply a higher or a lower grade of temperature in the stimulating object; it will seem "hotter" or "colder" than the same temperature on the normal side. If thermal sensibility is equally perfect on the two halves of the body the excessive response will begin as soon as the stimulus seems definitely cold. But it will not seem "hotter" on the affected side until the temperature of the stimulus reaches about 45° C. or above.

(*d*) *Visceral Stimulation.*

Discomfort in its purest form is produced by stimulation of the viscera, and we therefore compared the condition of testicular sensibility on the two sides in patients who showed this over-response to painful stimuli.

If care is taken not to pinch the scrotum, the characteristic testicular sensation, a sickening discomfort, can be evoked with no other accompaniment than a sensation of not unpleasant pressure. Many patients complained that the discomfort was more intense in the testicle of the affected side. Pressure sufficient to produce "a slight feeling" only on the normal side caused on the affected side a widespread expression of discomfort and brisk cremasteric movements of the opposite testicle.

The glans penis is endowed with a peculiar form of sensibility which differs normally from that of the skin in the absence of the more discriminative faculties (Rivers and Head). Heat and cold can be distinguished, but the finer grades of temperature are not appreciated. A prick causes a more widely spread sensation and is more unpleasant than over the rest of the normal skin. In fact, the glans penis is an organ endowed chiefly with the more affective elements of cutaneous sensibility, and it is therefore a peculiarly appropriate field for examination in cases which exhibit the over-reaction on the abnormal side.

When the glans is pricked with such an instrument as the algesimeter the same strength of stimulus may be necessary to evoke pain on the two halves of the organ; but the discomfort described by the patient and obvious from his expression is greater on the abnormal than on the normal portion.

(*e*) *Scraping, Roughness.*

All the stimuli considered so far contain for the normal person some obvious element of pain or discomfort. But in these cases of over-reaction on the affected side scraping the palm or the sole of the foot, moving a rough object over the skin or even rubbing the hairs may evoke an unpleasant sensation, unlike that from the normal half of the body.

The difference between the two sides is, as a rule, most evident when the observer gently scrapes with his fingers the patient's palm. Under normal conditions this is not unpleasant; but on the affected side the patient cries out and attempts to withdraw his hand. His face is contorted with discomfort. One patient complained: "It is a horrid sensation as if my hand were covered with spikes and you were running them in; it is not painful but very unpleasant." Frequently this sensation spreads widely, running up the arm or the leg, and is always started with peculiar ease from the sole of the foot (Roussy [34], Case 1).

This excessive response to scraping is frequently a striking feature during examination with the Graham Brown æsthesiometer. This instrument serves to estimate the appreciation of roughness by measuring the extent of the protrusion of a

tooth from a spherical surface which is necessary in order that it may seem "not smooth." We not uncommonly found that the "raking" sensation produced by this instrument was greatly exaggerated on the affected half of the body. But in no case was the threshold lowered. In some it was equal on the two sides and in others a greater protrusion was required to evoke a sensation, but in the large majority the discomfort produced was greater on the affected side.

Occasionally, even the rubbing of the smooth surface over the affected parts caused an uncomfortable tingling which confused the patient and rendered measurement impossible. In one case the instrument produced no sensation of roughness, but the tingling and discomfort were intense. Many of these patients complained that they could not be shaved on the affected cheek because it seemed as if the razor was "passing over a raw surface." Some objected to having the hair cut on the affected half of the head because of the discomfort, and others complained of the pain caused by the attempt to cut their nails.

Thus in cases where the affected parts react more strongly to painful stimuli it may happen that even scraping with the fingers, the application of rough objects to the skin, shaving, cutting the hair or nails may cause discomfort or produce a more unpleasant sensation than on the normal side.

(f) Tickling.

When the tips of the fingers are gently moved over the palm or the sole, or when the ears and other hair-clad parts are stimulated with cotton-wool, a tickling sensation can be produced in most normal persons. This is not unpleasant, and in some people the movements of withdrawal which result are accompanied by smiles of amusement. But in those cases characterised by an over-response to painful stimuli tickling is usually unpleasant. Several patients insisted that the sensation produced on the normal side was not disagreeable, whilst that from the abnormal parts was quite different and unpleasant. In all such cases the reaction was greater on the affected half of the body.

B.—*The Response to Pleasurable Stimuli.*

So far we have considered over-reaction of the affected half of the body to stimuli which are in themselves unpleasant, or are capable under certain conditions of evoking an unpleasant sensation. We were anxious to discover if sensations normally accompanied by a pleasurable feeling-tone also produced a similar over-reaction.

Unfortunately, the greater number of the methods applicable for the measurement of sensibility either produce discomfort or, like the tests for weight and for posture, evoke an entirely indifferent sensation. But in the milder degrees of heat we possess a measurable stimulus endowed with a pleasant feeling-tone. In the majority of cases, however, which showed an over-reaction to the uncomfortable aspect of a stimulus, sensation was at the same time more or less gravely lost; and this loss was particularly liable to fall upon that portion of the thermal scale which normally yields a sensation of pleasant warmth; in such cases this test is usually inapplicable.

On the other hand, in a few cases when thermal sensibility was abolished warmth applied over a sufficiently large surface evoked a feeling of pleasure. Thus one of our patients found a hot-water bottle pleasant and soothing to the affected foot, but did not recognise that it was warm until he touched it with some normal part. In the same way many patients found the warm hand of the observer unusually pleasant on the abnormal side, although no such manifestations of pleasure were produced when it was applied to normal parts of the body. In one case we were able to show that the patient could not recognise any thermal stimulus as such, and yet over the affected half of the chest large tubes containing water at from 38° C. to 48° C. evoked intense pleasure. This was shown not only by the the expression of her face but by her exclamations, "Oh! that's lovely; it's so soothing, so very pleasant." Temperatures of 50° C. and above, or of 18° C. and below, caused great discomfort exactly as in most of these thalamic cases.

Several of our patients, however, were able to appreciate heat as low as 34° C. on the affected half of the body. Here, whenever the sensation evoked was one of pleasant warmth, the pleasure was obviously greater on the affected side. In one case a tube containing water at 38° C. applied to the normal palm was said to be warm, but the patient cried out with pleasure when it was placed in the affected hand. His face broke into smiles, and he said, "Oh! that's exquisite," or "That's real pleasant." Another patient said, "It seems on both hands, but it is more soothing, more pleasant on the affected palm."

Cold has no pleasurable element—at any rate, during the greater part of the year in this country. As soon as a sensation of cold is produced it is said to be "colder" and "more uncomfortable" on the affected half of the body. The threshold, or point at which a stimulus is said to become cold, generally lies somewhere between 24° C. and 27° C., and as soon as the sensation of coldness is well developed this discomfort begins. So far we have been unable to find any temperature which produces a sensation of pleasurable cold.

Thus, in conclusion, we find that in cases where the pleasurable aspect of heat can be appreciated the pleasure is accentuated on the affected side, yet the threshold for the appreciation of heat is never lowered and may even be raised on the side of the excessive reaction.

C.—*The Behaviour of the Affected Half of the Body in States of Emotion.*

In the preceding sections we have seen that the two halves of the body respond differently to affective stimuli. But no one seems to have recognised that states of emotion may evoke different manifestations on the two sides; not only can pleasant and painful stimuli produce a stronger reaction when applied to the affected parts, but the two halves of the body may behave differently to mental states of pleasure and discomfort.

Music is peculiarly liable to evoke a different reaction on the two halves of the body. One of our patients was unable to go to his place of worship because he "could not stand the hymns on his affected side," and his son noticed that during the singing his father constantly rubbed the affected hand.

Another patient went to a memorial service on the death of King Edward VII. As soon as the choir began to sing a "horrid feeling came on in the affected side, and the leg was screwed up and started to shake." The characteristic so-called choreiform movements were a prominent feature in this case, and whenever the unpleasant sensation was evoked in the affected side these movements were accentuated. The singing of a so-called comic song left her entirely cold, but "A che la morte" produced so violent an effect upon the abnormal half of the body that she was obliged to leave the room. In this case indifferent sounds, such as the note of a tuning-fork or sound of a bell, produced no abnormal effect, and closing the ear of the affected side made no difference to the character or intensity of the response.[1]

A highly educated patient confessed that he had become more amorous since the attack, which had rendered the right half of his body more responsive to pleasant and unpleasant stimuli. "I crave to place my right hand on the soft skin of a woman. It's my right hand that wants the consolation. I seem to crave for sympathy on my right side." Finally he added, "My right hand seems to be more artistic."

Thus, not only does the abnormal half of the body respond more vigorously to the affective element of a stimulus, but an over-reaction can also be evoked by purely mental states. The manifestations of this increased susceptibility to states of pleasure and pain are strictly unilateral and may lead to many curious complications.

3.—THE LOSS OF SENSATION WHICH MAY BE ASSOCIATED WITH LESIONS OF THE OPTIC THALAMUS.

Associated with this over-reaction to painful stimuli, some loss of sensation will always be manifest on the affected half of the body. In some cases the amount of this loss is so insignificant that, as it can be discovered by measurement only, we can imagine the existence of the over-reaction without it. But up to the present time we have not seen a

[1] Occasionally, however, auditory stimuli produce an increased reaction on the affected side exactly in the same way as pain and extremes of temperature. Such a case was described by Merle [22], and we have also seen an instance of this condition. This patient complained that any continuous sound and all noises upset him. When a tuning-fork was held before either ear it evoked obvious discomfort and gradually became intolerable. At the same time the spontaneous movements became extremely violent. It was difficult to be sure that the fork placed before one ear was a more potent cause of discomfort and exaggerated movement in the affected arm than when it was placed before the ear of the opposite side; but after testing him on many occasions, we came to the conclusion that the effect was greater if the sound affected the ear of the abnormal side of the body. There was, however, no doubt that he disliked the sound more in this ear than in the normal one.

patient in whom this excessive response was not accompanied by some sensory loss. It may vary in amount from a diminution so slight that it is scarcely recognisable up to a destruction of all forms of sensibility so severe that only the grossest stimuli can be perceived.

(*a*) *The Appreciation of Posture and Passive Movement.*

With lesions of the optic thalamus and neighbouring parts the appreciation of posture and passive movement suffers more frequently than any other sensory quality. Sometimes the ordinary rough tests reveal no obvious defect, although measurement shows that the recognition of the position of the hand or the power of appreciating passive movement is less accurate on the affected side. In other cases these functions are completely abolished. Between these two extremes all grades of diminished appreciation of posture and of passive movement could be discovered. These two functions were always affected together, except in two cases where the defect in the appreciation of passive movement was slight and lay close to the limits of experimental error.

(*b*) *Tactile Sensibility.*

Here again we find the same extraordinary divergence in the amount of the sensory loss. In five cases the tactile threshold, measured with von Frey's hairs, was identical on the two hands, but in the majority some more or less grave deviation from the normal was discovered on the affected side. Sometimes the affected parts may be entirely insensitive to the tactile hairs, and even considerable pressure may not be appreciated. But frequently the loss of tactile sensibility is much less extreme, and is manifested simply by a raised threshold.

Another difficulty that may prevent the demonstration of a tactile threshold, by means of von Frey's hairs or with graduated pressure, is the occurrence of involuntary movements. Many of these patients show curious irregular movements which may not always be present, but are liable to start when the affected side is stimulated. These movements arising involuntarily may be mistaken under these conditions for touches. The longer the testing is continued the more accentuated these movements become, and all demonstration of a threshold is then impossible.

To sum up, the tactile threshold may be normal on both sides in the cases with which we are now dealing; or it may be raised to a greater or less extent, even up to complete abolition of sensibility to measured tactile stimuli. Accessory sensations, or the misapprehensions of involuntary movements, may confuse the records, but the loss of threshold and irregular response, so characteristic a consequence of cortical disease, is not found as the result of lesions at this level of the nervous system.

(*c*) *Localisation.*

The power of recognising the position of a stimulated spot was more or less grossly affected in 12 out of 24 cases. This faculty may be so profoundly disturbed that a touch on the hand is referred to the same half of the face or trunk. More commonly the patient complains that he has no idea where he has been touched. "I feel you touch me but I can't tell where it is; the touch oozes all through my hand." Although the method we have generally used forces him to recognise that he has been touched somewhere on the hand, the patient frequently gives up all attempts to determine the spot, saying, "I have no idea where you touched me."

Wherever localisation is affected the unpleasant sensation evoked by painful stimuli may spread widely over affected parts. When, for instance, the sole has been pressed with the algometer, the pain may occupy the whole of the leg below the knee, and the patient does not recognise that the instrument was applied to his foot.

(*d*) *Heat and Cold.*

Out of 24 patients who showed signs of a thalamic lesion 22 responded excessively to the unpleasant aspect of heat and cold. In 9 of these cases the threshold for thermal stimuli was the same on the two sides, and but for the over-response sensibility to heat and cold appeared to be normal; the range of discrimination was identical on the two halves of the body. This class is peculiarly interesting, for in them may appear the remarkable over-response to pleasurable heat we have already described.

But not infrequently all appreciation of heat and cold is abolished, and ice and water at over 50° C. evoke nothing but discomfort. This sensation is the same whichever of the two extremes is used; the patient cannot tell the difference and may not recognise the cause of the unpleasant sensation.

Occasionally the insensibility is less profound and temperatures below 26° C. and above about 40° C. may evoke a response from the affected half of the body. But this response may be the same for heat and cold; water above 40° C. and below 26° C. produces the same sensation and may therefore be called indiscriminately hot or cold.

Throughout all these cases, where the loss of thermal sensibility was not absolute, a threshold could always be determined. It might be the same on the two sides, or it might be more or less raised on that half of the body which showed an excessive response. But never did we find that remarkable loss of threshold and inability to discriminate between two temperatures, both of which were recognised to be hot or to be cold, so characteristic a feature with cortical lesions.

(*e*) *The Compass-test.*

In order that this test may be applied the patient must of necessity be able to recognise that he is being touched; tactile sensibility must not be gravely diminished. But many of the patients who reacted excessively to painful stimuli on the abnormal side were so insensitive to touch and pressure that the contact of two points produced no sensation and the compass-test could not be employed.

Another disturbing element in these cases is the widespread unpleasant tingling frequently evoked by a firm touch; this tingling is liable to distract the patient's attention and confuse the records greatly.

Excluding these sources of error, a considerable number of cases still remain in which the power of recognising the "two-ness" of the compass-points was disturbed although each touch evoked a sensation of contact. But by widening the compasses a distance could usually be found at which a perfect series of answers could be obtained, and the records improved each time the distance between the two points was increased. Thus in such cases it is possible to obtain a true threshold.

In conclusion, we have found that the compass-test cannot be applied in many of these cases owing to the gross loss of tactile sensibility or to the confusion produced by the abnormal tingling. But whenever the measured tactile threshold is the same on the two halves of the body the power of discriminating two points will be unaffected; and yet the two faculties are not directly dependent, for two pricks cannot be discriminated more easily than the contact of two blunt points.

(*f*) *The Appreciation of Weight.*

Throughout this research we have adopted three methods of testing the appreciation of weight. A weight is placed in each palm and the patient by moving them up and down "weighs" them and estimates which is the heavier. Secondly, a weight is placed on some part of the fully supported hand, removed, replaced rapidly by another weight of the same size, and the patient chooses the heavier. Lastly, a weight is placed upon the hand and further weights are added or subtracted. The patient replies whenever he recognises that the weight has become heavier or lighter. Now it is obvious that the last two methods depend mainly upon an appreciation of relative pressure, whereas the first demands a power of estimating movement and the force employed in lifting the hands.

At the level of the nervous system with which we are now engaged this difference comes out in a remarkable manner. In some cases the only discoverable loss of sensation consisted in a diminished recognition of posture and passive movement, and correlated with this loss was an inability to distinguish weights placed simultaneously on the unsupported hands; and yet the patient may be able to recognise the relation between two weights, placed one after the other on the affected hand when fully supported. Conversely, any diminution of tactile sensibility at once affects the power of appreciating relative pressures, and so interferes first with the estimation of weights applied consecutively, and later even with the ability to recognise whether an object resting on the palm has become heavier or lighter.

Thus at this level of the nervous system the power of estimating the relation between two weights depends on the integrity of both tactile and postural impulses. The faculty of estimating the relative weight of two objects placed one

in each unsupported hand demands a correct appreciation of posture and movement. But appreciation of two weights placed consecutively on the supported hand, and the power of recognising addition to, or removal from, the weight of an object lying in the palm, require a normal tactile sensibility.

(*g*) *The Appreciation of Size, Shape, and Form in Three Dimensions.*

No tests for the recognition of size, shape, or form can be applied unless the patient is able to appreciate the contact of objects placed in his palm. In five of our cases this was impossible owing to gross loss of tactile sensibility, whereas on the contrary in six cases the lesions which produced an over-response to painful stimuli had in no way affected the power of recognising size, shape, or form.

Between these two extremes lies a group in which all three forms of recognition were more or less gravely defective. Although the defective recognition of size, shape, and form, which may accompany the over-response to painful stimuli, appears at first sight to resemble that due to cortical lesions, more careful examination shows that they may differ fundamentally from one another. Ordinary clinical tests employed in the usual rough manner are incapable of demonstrating this difference. But when a series of tests are carefully carried out the patient is able, in most cases, to recognise a difference in size, provided it is sufficiently large; a true difference-threshold can be obtained. He does not give up all attempts to estimate the relative size of the test-objects, saying, as in the case of a cortical lesion, "I have no idea." He may make mistakes in their relative size or may believe that the two objects are equal, but retains an impression that they possess a size to be compared. Ultimately, if the difference between them is made sufficiently great, his answers grow increasingly more accurate.

Unfortunately we have no method of reducing the tests for shape and form to measure in the same way; for increasing the size of objects used for testing shape beyond certain limits prevents their uniform application to the palm, and any considerable reduction makes it impossible to recognise them on the normal hand. Even the size of the objects used as tests for form in three dimensions cannot be varied greatly, since it is necessary that the patient should be able to roll them between his fingers and palm.

In spite of these difficulties the patient usually attempted to give some name to the object, provided tactile sensibility was not greatly impaired, and he could move it to and fro in his hand. Not uncommonly he said, "I have an idea of the shape, but it seems numb." Moreover, in the majority of instances a certain number of right answers were given, especially to the easier tests, such as the circle or the sphere, and the familiar objects commonly used in clinical examination were frequently recognised.

Thus, in conclusion, we find that in these cases the recognition of size, shape, and form may be intact, or more or less gravely affected. In some instances this loss of recognition is due to gross defects in tactile sensibility. But in a considerable group of cases the difference-threshold is raised; here all idea of size, shape, and form is not abolished, as in the cortical cases, but a greater difference than normal is necessary before it can be appreciated. In the same way the patient retains an idea that the objects have a shape and form, but finds difficulty in recognising what it may be.

(*h*) *Vibration.*

The loss of sensation must be unusually gross before the vibrations of a tuning-fork cease to be appreciated. In three cases only was the affected half of the body insensitive to this stimulus, and in all of them other forms of sensation were gravely affected.

Usually the vibrations of the tuning fork are appreciated on both halves of the body, but the stimulus appears to last a shorter time on the abnormal side. If the tuning fork is placed upon some point of the affected side and as soon as it can no longer be appreciated is rapidly transferred to a corresponding part on the normal half of the body, the patient will continue to recognise the vibration for a further period, which may even extend to 15 seconds. This shortened appreciation of the tuning fork is one of the most characteristic features of the loss of sensation associated with the over-response to painful stimuli. It occurred in 15 of our cases, and was independent of that unpleasant feeling tone, evoked by vibration, of which we have already spoken. At the same time the patient complains that the vibrations are "not so plain" on the abnormal half of the body and in certain cases the fork seems to be vibrating less rapidly on the affected side.

(*i*) *Roughness.*

In three cases only was the loss of sensation sufficiently gross to prevent the appreciation of roughness produced by Graham Brown's æsthesiometer. This instrument with its graduated projection is peculiarly liable to evoke an unpleasant sensation, and occasionally confusion is produced because even the smooth surface of the instrument may evoke a widespread tingling. But in most cases it is easy to show that the threshold for the appreciation of roughness as measured with this instrument is the same on the two halves of the body.

(*k*) *Summary of the Loss of Sensation.*

We can now sum up the forms assumed by the loss of sensation which may accompany the over-reaction to affective stimuli in these cases.

No sensory function is so frequently affected as the appreciation of posture and the recognition of passive movement. The amount of this loss varies greatly from a scarcely measurable defect to complete want of recognition of the posture of the limbs on the abnormal half of the body.

Tactile sensibility is frequently diminished; but, excepting in a few cases where all appreciation of contact was destroyed, a threshold could be obtained. It was always possible to show that increasing the strength of the stimulus improved the character of the answers unless the observations were confused by the disagreeable tingling or other accessory sensations.

Localisation of the spot touched was defective in half the cases where sensation was sufficiently preserved to carry out accurate tests. This inability to recognise the site of stimulation was equally great whether the patient was pricked or touched. In cases where localisation was gravely affected, the disagreeable sensation, so easily evoked, tended to spread widely on the abnormal half of the body. A prick on the hand may cause an extremely painful sensation in the cheek or side, and sometimes the patient simply recognised the stimulus as a change within himself, and did not refer the discomfort from which he suffered to the action of any external agent.

Sensibility to heat and cold may show all degrees of change from total loss to a slight increase of the neutral zone. Heat and cold are not dissociated; and if one form of sensation is lost, the other will be gravely disturbed. The apparent exceptions arise from a misinterpretation of the sensation evoked on the affected half of the body by high or low temperatures.

Not infrequently the compass-test cannot be carried out because of the gross loss of sensation and inability to recognise contact; but whenever this method can be applied a threshold can be worked out, and widening the distance between the points increases the accuracy of the answers.

The power of estimating the relation between two weights is frequently disturbed on the abnormal half of the body. If the appreciation of posture and movement is affected, the patient can no longer recognise the identity or the difference of two weights placed in the unsupported hands. But so long as tactile sensibility is not diminished, he can still estimate the relation between weights applied one after the other to the same spot, and can recognise the increase or diminution in weight of an object already resting on the hand.

The appreciation of relative size is often disturbed in these cases, but with care it is usually possible to demonstrate a difference-threshold. Shape and form in three dimensions are frequently not recognisable on the affected hand. But if tactile sensibility is not grossly affected, the patient usually retains an idea that the object possesses a form, and may obtain a considerable percentage of right answers.

Vibration of the tuning fork was recognised by all but three of our patients. In almost every case, however, the length of time during which it was appreciated was shorter, and sometimes the rate of vibration was thought to be slower, on the affected half of the body.

Roughness as tested with Graham Brown's æsthesiometer was always recognised, except in three cases where the loss of all forms of sensation was extremely severe. Usually the threshold was the same on the two sides, but it was occasionally raised on the affected hand.

(To be concluded.)

RUPTURE OF THE UTERUS:

A SERIES OF EIGHT CASES, INCLUDING THREE CASES TREATED SUCCESSFULLY BY OPERATION.

BY G. BLACKER, M.D. LOND., F.R.C.P. LOND., F.R.C.S. ENG.,

OBSTETRIC PHYSICIAN TO UNIVERSITY COLLEGE HOSPITAL AND THE GREAT NORTHERN CENTRAL HOSPITAL.

THE best method of treating cases of rupture of the uterus is still one of the problems of obstetric medicine upon which a good deal of difference of opinion exists; nor, indeed, is it likely that this difference will be entirely overcome, since these cases may vary greatly both in the severity of the symptoms and in the degree of the injury. If we are to be in a position to come to any certain conclusion, it will be necessary for a considerable number of cases to be fully recorded from lying-in hospitals and clinics, so that by a comparison, so far as this can be done, of the results obtained by different modes of treatment under much the same conditions, we may be able to formulate rules to guide us in our treatment of these difficult cases.

I propose in this paper to put on record the cases which have occurred in the extern maternity department of University College Hospital during the 18 years from Jan. 1st, 1894, to Nov. 30th, 1911. During this period 33,781 women have been confined in the department, and among these cases there were eight cases of rupture of the uterus, or a frequency of 1 in 4222.

The details of the cases are shortly as follows.

CASE 1 (Reg. No. 690).—The patient was delivered spontaneously in the extern maternity department on March 27th, 1894, the child being born before the arrival of the student called to the case. She had had five previous normal pregnancies. After delivery she became markedly collapsed, and complained of severe pain in the lower part of the abdomen on the left side. With treatment she recovered to some extent, but died six hours after her confinement, the exact condition not having been diagnosed. At the post-mortem examination an incomplete tear 6 cm. long of the left side of the cervix was found extending into the lower uterine segment, and opening up the base of the broad ligament. The lower end of the tear was situated 1½ cm. above the edge of the posterior lip of the cervix. The presentation was a vertex, the labour rapid and apparently quite normal, and on this account I concluded wrongly that the case was probably not one of rupture of the uterus. The specimen is in the University College Hospital Medical School Museum, No. 731.

CASE 2 (Reg. No. 1922).—The patient was confined in the extern maternity department on August 25th, 1894. She had had six children, all delivered with great difficulty with forceps. The true conjugate measured 3¼ inches. The child, weighing 8 lb. 10 oz., was delivered by the craniotractor after perforation, forceps having failed. On examination a tear in the right side of the cervix, passing into the right broad ligament, was found. The patient's condition did not admit of any operative treatment, and she died ten hours after delivery. (University College Hospital Medical School Museum, specimen No. 726.) The case is fully reported in the Transactions of the Obstetrical Society of London, Vol. XXXVI., p. 316, 1894.

CASE 3.—This case, under the care of Dr. Herbert Spencer, has been reported by him in the Transactions of the Obstetrical Society of London, Vol. XLII., p. 18, 1900. The patient, a multipara with a contracted pelvis, the conjugata vera measuring 3½ inches, was delivered by podalic version, on account of a shoulder presentation, on Oct. 29th, 1896. The child was delivered alive, but after delivery the patient became greatly collapsed and bled freely, and after removing the placenta a tear was found extending into the broad ligament. No communication with the peritoneal cavity could be found. The cavity in the broad ligament was plugged with iodoform gauze, and the woman made an excellent recovery.

CASE 4 (Reg. No. 250).—The patient, a six-para, was delivered in the extern maternity department on Feb. 3rd, 1897. The left shoulder was presenting, and the arm was outside the vulva. The child was easily delivered by internal version by the obstetric assistant. The patient became markedly collapsed immediately after delivery, and vaginal examination revealed an extensive tear of the left side of the cervix and lower uterine segment extending into the peritoneal cavity. An attempt was made to plug the tear with iodoform gauze, but the patient died 45 minutes after delivery. (University College Hospital Medical School Museum, specimen No. 734.)

CASE 5 (Reg. No. 1352).—The patient, aged 32, was admitted to University College Hospital on July 3rd, 1904. She was a very fat woman with a pendulous abdomen, and was delivered by forceps of a stillborn child weighing 13½ lb. The shoulders and trunk were extracted with considerable difficulty. On examination after delivery it was found that there was a large tear in the lower uterine segment and in the vagina, on the left side, opening into the peritoneal cavity. The tear and the vagina were plugged with iodoform gauze under an anæsthetic and saline transfusion was carried out, but the patient died six hours later. (University College Hospital Medical School Museum, specimen No. 722.)

The three following cases were treated by operation and recovered, and they are therefore recorded in greater detail.

CASE 6 (Reg. No. 247).—*Complete rupture of the uterus, following delivery by traction on the foot in a case of placenta prævia, at the fifth month of pregnancy; suture of the tear; recovery.*—The patient, aged 40, a multipara, was admitted into University College Hospital on Jan. 26th, 1911. She had had three children. At the first confinement a part of the placenta was retained and had to be removed manually. After the second child she was laid up in bed for three weeks, and at her third confinement she sustained a bad tear of the perineum and rectum. Her last period had occurred at the beginning of September. About the middle of December the patient began to bleed, and this continued almost every day until three weeks before admission to the hospital. Since this date she had been confined to bed with continuous hæmorrhage.

On admission to the ward the patient's general condition was good; some vaginal hæmorrhage, however, was going on. The uterus was the size of the organ at the twentieth week of pregnancy, tense, and somewhat cystic to the feel on palpation. No fœtal parts could be felt and no fœtal heart sounds heard.

As the hæmorrhage continued and the cervical canal admitted two fingers, the provisional diagnosis of a placenta prævia having been made, a sound was passed and the membranes were ruptured at 2 P.M. on Jan. 26th. Slight bleeding continued, but only very slow progress was made in the dilatation of the cervix. At 8.45 P.M. on the 27th the cervix admitted 2½ fingers, and a small foot could be felt presenting. The placenta could be readily felt on the anterior wall of the uterus reaching to the internal os. Chloroform was administered, the other foot was brought down by the obstetric assistant, and the fœtus was readily extracted with some traction. During this procedure, however, the cervix was apparently badly torn, and severe hæmorrhage followed the delivery of the fœtus. As this could not be controlled by massage of the uterus the assistant introduced his hand into the uterus to extract the placenta, and apparently during this manœuvre the tear in the cervix was prolonged into the lower uterine segment, and the peritoneal cavity was opened up. A gauze plug was packed into the tear, and I was sent for.

When I saw the patient at 9.20 P.M. her general condition was good. There was some hæmorrhage going on from the vagina, and on examination a tear was found in the posterior lip of the cervix on the right side involving the lower uterine segment, with an opening into the peritoneal cavity through the lateral portion of the pouch of Douglas, readily admitting four fingers. The torn lips of the cervix were drawn down with vulsella, after the peritoneal cavity had been swabbed out, and the edges of the tear were approximated with three thick catgut sutures passed from above down. A plug of iodoform gauze was then placed in Douglas's pouch below the tear in the uterus, and the vagina was also plugged with iodoform gauze. The vaginal plug was removed 20 hours later and the plug in the peritoneum on the morning of the third day. At this time a small plug was placed between the lips of the opening in Douglas's pouch, and this was finally removed on the seventh day.

For the first four days after the operation the temperature was slightly raised, the highest point reached being 101·4° F. The patient made an uninterrupted recovery, and left the hospital with the wounds soundly healed on the seventeenth day.

CASE 7 (Reg. No. 1105). *Complete rupture of the uterus following an attempt at the performance of version for a transverse presentation; Cæsarean section followed by total hysterectomy; recovery.*—The patient, 38 years of age, was admitted into University College Hospital on April 6th, 1911. She had had six children and no miscarriages. All the labours had been normal, except that with the second child the shoulder presented. The last period had occurred at the end of July, 1910. Labour pains started at 4 A.M. on April 5th, at about the thirty-sixth week of pregnancy, and the membranes ruptured at 10 A.M. on the 6th.

When the patient was seen by the obstetric assistant at her own home he found that the right arm and the pulseless cord were prolapsed into the vagina. Uterine contractions were present, but feeble. The mother's pulse was 80. The cervical canal was dilated to the size of a crown piece, and an attempt was made by the obstetric assistant to replace the arm and cord with a view of performing, if possible, bipolar version. On attempting to replace the arm there was suddenly a smart hæmorrhage, and the operation was accordingly abandoned. On a further examination a tear was found in the anterior and lateral fornix large enough to admit the whole hand into the peritoneal cavity.

The patient was admitted into the hospital from the extern maternity department about 2.30 P.M., a large iodoform gauze plug having been inserted into the tear. On examination the right arm of the child was found to be prolapsed into the vagina with the cord, the child lying with its back posterior, and the head in the right iliac fossa. The patient's condition was now very grave, and she was practically pulseless, blue, and cold. The tear was found to be situated in the utero-vesical pouch mainly to the left of the middle line. The uterus was not tetanically contracted. Although the child was obviously a small one, I felt that any attempt to deliver by version would certainly increase the extent of the tear, and it was therefore decided to perform abdominal section. Two pints of normal saline solution were transfused into the left median basilic vein, and the abdomen was prepared with iodine.

On opening the peritoneal cavity a considerable quantity of free blood was found. The tear in the anterior fornix was complete, involved the cervix to a slight extent to the left of the middle line, and the child's left shoulder was seen presenting in the tear. The left broad ligament was almost entirely torn through, so that the left Fallopian tube was seen passing in an arch-like manner to the left side of the pelvis. The peritoneum was cracked in several places on the anterior surface of the uterus to the right of the middle line, and hæmorrhage had occured under the peritoneum.

The uterus was rapidly incised by enlarging the tear in the anterior wall of the cervix upwards to a sufficient extent and the child and placenta were extracted. The broad ligaments were clamped, leaving the right ovary and removing the left. The tear in the utero-vesical pouch of peritoneum was continued round to either side with scissors, the uterine arteries were clamped, and the uterus was removed by cutting across the posterior vaginal wall. The clamps were replaced by silk ligatures. There was very little hæmorrhage during the operation. The vesical flap of peritoneum was sewn to the rectum over a plug of iodoform gauze brought out through the vagina, and the abdomen was closed with through-and-through silkworm gut sutures, with interrupted silk mattress sutures for the fascia, and continuous horse-hair suture for the skin.

The operation lasted 40 minutes. Two or three pints of saline solution were left in the abdomen at the end of the operation. A

hypodermic injection of 10 minims of pituitary extract was administered. The patient's condition at the end of the operation was very good, the pulse about 80, and of fair volume. The fœtus was a small macerated child weighing 2lb. 10 oz.

Three hours after the operation the patient was put up in Fowler's position, and except for a little bronchitis she made a rapid recovery and left the hospital quite well on the twenty-eighth day. The vaginal plug was loosened a little each day, and it was finally removed under gas on the fifth day. The temperature remained slightly elevated for the first ten days after the operation, the highest point reached being 101·2° F., whilst the pulse never exceeded 100 per minute. (University College Hospital Medical School Museum, specimen No. 735*a*.)

CASE 8 (Reg. No. 1116). *Complete rupture of uterus at full term; cephalic presentation; delivery by version; total abdominal hysterectomy; recovery.*—The patient, 34 years of age, was admitted into University College Hospital on April 8th, 1911. She had had three children in two confinements, and on each occasion the labour was normal. She was seen at 2 P.M. on the 7th by the obstetric assistant on duty in the Extern Maternity District on account of a prolonged second stage. Labour had commenced at 9 P.M. on the 6th, and when seen the cervix was fully dilated. The head was in the pelvic cavity, and an attempt was made to apply the forceps. On the introduction of the lower blade, however, the head appeared to recede out of reach above the pelvic brim and severe vaginal hæmorrhage occurred. On further examination a hand was found to be presenting, and what was thought to be the edge of the placenta was felt; there had been a considerable amount of hæmorrhage during the first stage. A foot was brought down and the child was delivered stillborn at 4 P.M. with some little trouble, the arms becoming extended. No undue force appears to have been used in introducing the blade of the forceps, and no undue difficulty was experienced in bringing down the leg. No contraction of the pelvis was present. The placenta was expressed 20 minutes after the delivery of the child.

The patient complained of severe abdominal pain with the onset of the severe hæmorrhage soon after the head receded. The possibility of a rupture of the uterus having occurred was not realised, and when the woman was seen by the obstetric registrar next day at 11 A.M. she was found to be collapsed and dyspnœic, with blue lips, and gave a history of having bled fairly freely all night. The pulse was very small, 124, and the abdomen was distended and very tender. She had vomited several times, and the bowels had not acted. On vaginal examination a tear could be felt passing into the peritoneal cavity. The patient was at once brought up to the hospital in a cab.

On admission at 12 noon on April 8th on pelvic examination I found a large tear in the left postero-lateral vaginal fornix and the cervix, through which the hand could be passed into the peritoneal cavity; a catheter was passed and 8 ounces of clear urine were drawn off. The uterus, well contracted, lay to the right of the middle line. The patient was put to bed for a couple of hours to recover from the shock of moving her to the hospital.

At 2 P.M. abdominal section was performed, the abdomen being prepared with iodine, a simultaneous transfusion of 1½ pints of normal saline solution into the left median basilic vein being carried out. A hypodermic injection of digalen (6 minims), pituitary extract (15 minims), and ernutine (10 minims) was also administered. On opening the peritoneal cavity the intestines were found considerably distended and injected, the serous coat was dull and covered in places by patches of lymph; no pus, however, was present. There was a good deal of free blood in the peritoneal cavity, and the tear was found to extend through the cervix and the lower uterine segment, tearing through the left broad ligament into the peritoneum. A large hæmatoma was present in the cellular tissue on the left side.

The remains of the left and the right broad ligaments were clamped internal to the ovaries, and the bladder was turned down. The uterine arteries were then clamped, and the whole uterus was removed, the vessels being subsequently tied with silk ligatures. The peritoneal cavity was swabbed out, and an iodoform gauze plug was passed from the peritoneal cavity into the vagina, and another was brought out from the stump of the vagina through the lower angle of the abdominal wound. The abdomen was closed with through-and-through silkworm gut sutures, silkworm gut mattress sutures for the fascia, and a continuous horse-hair suture for the skin.

The operation lasted 35 minutes. The condition of the patient improved somewhat under the anæsthetic, the pulse at the conclusion being of fair volume and 136 per minute. The operation was rendered difficult by the distended condition of the intestines.

On the patient's return to the ward she was placed in Fowler's position. During the afternoon and evening there was very frequent vomiting. At 11 P.M. the pulse was very weak, and she was complaining of severe spasmodic pain in the upper part of the abdomen, which was very tender and distended. A hypodermic injection of pituitary extract (15 minims) every eight hours, strychnine (5 minims), and digalen (6 minims) every four hours, and eserine salicylate (4 minims) every six hours, was ordered. One grain of calomel and 1 grain of elaterine were given by the mouth.

During the next day (April 9th) the vomiting was almost continuous and the abdomen was more distended. At midday a soap-and-water enema was given, and flatus was passed with some liquid fæces. The pulse was now 145 and very small. During the afternoon continuous rectal injections of saline solution and glucose were given, about two pints being retained. After this very severe paroxysmal pain was complained of, coming on every two or three minutes and lasting about the same time, and the patient became very restless. The digalen was now stopped owing to the vomiting.

At 5 P.M. the pain was so severe that the woman was shouting in agony. The pulse was 165 and very small. An intravenous infusion was started, and about half a pint had been run in slowly when the patient became collapsed and the pulse at the wrist failed altogether. The infusion was stopped and 10 minims of adrenalin chloride were given intravenously. The pulse gradually returned, as did the pain so severely that a hypodermic injection of heroin (5 minims) had to be given. At 7 P.M. a large liquid motion was passed, the pain became less severe, and the patient more comfortable.

The continuous rectal injection was continued for 3½ hours during the night, and by next morning the condition had much improved. The vomiting ceased, and from this time the pulse-rate became progressively slower and better in quality, and the woman gradually recovered. For some days the bowels were very loose, and the temperature remained elevated for 24 days, varying between 99° and 101·8° F.

The plugs were removed under gas on the fifth day, and the patient left the hospital quite well on the thirty-eighth day after the operation.

The uterus, measuring 18 × 13½ × 11 cm., shows a tear extending for 10 cm. above the anterior lip of the left side, opening into the peritoneum; it does not extend quite to the top of the broad ligament. The cervix is infiltrated with blood, and the posterior lip is much thickened, measuring 3 cm. antero-posteriorly. The wall of the body is also thickened, measuring 5·5 cm. (University College Hospital Medical School Museum, Specimen No. 735.)

Remarks.

These three cases present several points of considerable interest. The first is a good example of traumatic rupture involving the cervix and lower segment, undoubtedly due to the forcible extraction of the fœtus through the partly dilated cervix, and the subsequent enlargement of the tear by the introduction of the hand for the purpose of removing the placenta.

The second case is an example of the same variety of rupture, but due to attempts at the performance of version in what was probably an impacted shoulder presentation, and affecting mainly the vaginal vault, although the left broad ligament was extensively torn as well. Von Winckel maintains that such tears are especially likely to occur in cases of transverse presentation; and no doubt in these cases, owing to the faulty position of the fœtus, there is a liability to marked over-distension of the vaginal fornix, either anterior or posterior.

The etiology of the third case is difficult to explain. On the whole, it appears to be a case of spontaneous rupture due to undue prolongation of the second stage in a multipara. As the head was in the pelvic cavity and the cervix was fully dilated, it is unlikely that the introduction of the forceps played any part in the production of the tear.

Although all three cases were complete tears, they illustrate very varying degrees of severity as regards the symptoms the patients presented. In the first case the general condition of the patient was good, in the second the condition of the patient was very grave, while the third woman appeared to be moribund at the time of the operation. Further than this, there is the interesting contrast that the second patient was still undelivered, while in the case of the third the operation was performed upon a patient who had all the physical signs of commencing peritonitis 24 hours after the time at which the rupture of the uterus probably occurred. The fact that very severe tears of the lower uterine segment may occur in cases of placenta prævia is, of course, well known, but the fact is apt to be overlooked that such tears may be produced at the fourth or fifth month of pregnancy almost as readily as at full term, and often to a degree which seems almost impossible when the consistence even of the head of the fœtus at this period of development is considered.

Of this series of eight cases, in two the tear was incomplete and in six complete. Of the former, one in which the shock alone was treated, the condition remaining unrecognised, died, while the second, Dr. Herbert Spencer's case, recovered after plugging. Of the six cases of complete tears three died and three recovered. Of the fatal cases two were treated by plugging, in one the shock alone was treated, while the three successful cases were all operated upon, one by vaginal suture and two by hysterectomy. The total mortality was 50 per cent. The series of cases is too small to allow of any deductions being drawn, but it illustrates the frequency of this complication of labour—viz., 1 in 4222 confinements—in an extern maternity department among the poor of London, and the cases are fair types of the different varieties of rupture of the uterus.

The problem we have to consider at the present day in regard to the treatment of these cases is concerned mainly with two points—namely, the employment of gauze plugging or drainage per vaginam, so-called conservative treatment, and the performance of abdominal section, with or without removal of the uterus. The particular method of dealing with the uterus after the abdomen is opened is more or less of a detail, and the degree of shock is not likely to be much more increased once the abdomen is opened by suturing the peritoneum over a torn uterus, or by suturing the tear itself, than by the removal of the damaged organ. The real point at issue is, Should we, or should we not, in all complete tears—and for the moment I propose to consider these chiefly—perform an abdominal section, or possibly vaginal hysterectomy, or should we content ourselves with vaginal drainage or plugging?

There are certain conditions in which an abdominal

section is essential—namely, when the child has escaped through the tear into the abdominal cavity, or in most instances where the placenta, after the child has been delivered, is found to have passed through the rent out of the uterine cavity. Even in cases of complete rupture of the uterus, however, the child does not escape into the abdominal cavity so often as might be expected from the statements of some writers. Thus, this did not occur in any one of our cases of complete tear, while in the ten cases recorded by Dr. A. L. Smith[1] the child in two, and the placenta in four, is stated to have been in the peritoneal cavity. Of the three cases recorded by Dr. T. W. Eden,[2] in one the child had escaped from the uterus and in two the placenta. Of Lobenstine's[3] 46 cases of complete rupture the child was in the abdomen in seven instances, or in 13·5 per cent., and the placenta, so far as is stated, in four. The exact position of the placenta is not given in all the cases, but apparently it escapes more frequently from the uterus than does the child.

It is obvious, then, that in the majority of cases of complete rupture of the uterus the child is still in the uterine cavity, and our decision as to the best treatment must be made without the guidance afforded by the presence of the child or placenta in the abdominal cavity. In the greater number of these cases the presence of a tear is only recognised after the child has been delivered, or before it is delivered but while it is still in utero.

The dangers these patients are exposed to are, of course, shock, hæmorrhage, and sepsis. The first is the main cause of death occurring soon after delivery, and in complete tears is usually very severe. Indeed, many patients succumb to shock before it is possible to carry out any treatment at all. This element of profound shock is one of the most important factors, and is the main reason of the heavy mortality which attends the treatment of these cases by abdominal section.

The amount of hæmorrhage that occurs varies very considerably. Of my three cases operated upon, in only one was the hæmorrhage at all severe—namely, in the third case. The danger from hæmorrhage is not only immediate but also remote—that is to say, the shock of the rupture is often greatly aggravated by profuse hæmorrhage occurring at the time, and there is a very great risk, if the hæmorrhage ceases spontaneously, as it sometimes does, that as the shock passes off it will recur and kill the patient.

The exact amount of blood lost is difficult to determine, as the blood escaping externally is usually not measured, and the amount of blood present in the peritoneal cavity or outside the peritoneum is difficult to estimate in the hurry of an abdominal section. The majority of the cases bleed considerably either internally or externally, and no doubt slow oozing of blood often continues, especially into the subperitoneal tissues, after the external hæmorrhage has ceased.

Some writers—Eversmann,[4] for instance—maintain that, as in a large number of the cases, the uterus after the delivery of the child usually contracts and retracts, with a surprising degree of efficiency, the hæmorrhage is arrested by the closure of the vessels in the uterine walls. This contention does not, however, hold good. In the first place, a great deal of the hæmorrhage undoubtedly occurs while the child is still in utero, even when it ultimately escapes into the peritoneal cavity; and in the second place, since the tear in most cases involves the cervix and lower uterine segment, hæmorrhage no doubt continues, as it does in lacerations of the cervix, even although the fundus of the uterus may be well contracted.

An analysis of Lobenstine's 46 cases with regard to this point shows that of 43 in which the information is given, in 30 the hæmorrhage was profuse or severe, and in 13 moderate. Eden suggests that dangerous hæmorrhage occurs in over 40 per cent. of cases of rupture of the uterus; it is, of course, difficult to define what amount of hæmorrhage is dangerous, but probably we are right in saying that the great majority of cases at any rate of complete rupture are accompanied by profuse or severe hæmorrhage. In one of Smith's cases at the post-mortem examination it was estimated that there were between four and five pints of blood present in the peritoneal cavity, while in one of Lobenstine's cases the abdomen is described as being full of blood.

Whatever mode of treatment, then, is adopted, it must be one which will enable us efficiently to arrest the hæmorrhage which may be occurring at the time the patient is seen, and also to guard her from any recurrence of the bleeding later on. The large part played by recurrent hæmorrhage in causing the death of these patients is brought out by Ivanoff's[5] figures, for he has shown, as Eden points out, that the great majority of deaths from hæmorrhage occur not immediately, but within 2 to 12 hours after the rupture—namely, after repeated hæmorrhage or oozing has occurred.

Besides the immediate risk of shock and hæmorrhage and the remote risk of recurrent hæmorrhage these patients all stand a very great chance of succumbing to septic peritonitis or general septic infection, and we are justified in assuming that the main factors in the causation of this risk are the presence of the damaged and possibly infected uterus, and the presence of blood free in the peritoneum or in the cellular tissues.

Any mode of treatment, then, which we may select for dealing with this grave accident of child-bed should fulfil three postulates—viz., it should not increase the shock, it should provide for the arrest of hæmorrhage, both immediate and remote, and it should preserve the patient as far as possible from the risk of dying from septic infection.

Those obstetricians who recommend that cases of rupture of the uterus should, whenever possible, be treated by gauze packing or the provision of free drainage through the vagina, maintain that this method does not increase the shock, that hæmorrhage is prevented by the pressure of the gauze, and that the risk of septic infection is lessened by the provision of drainage through the vagina, and by the avoidance of any great amount of manipulation. Let us now for a moment examine the truth of these three contentions.

The first must be at once conceded; there can be no doubt that gauze packing is the least likely of any procedure to increase the shock.

That gauze plugging in cases of incomplete rupture will probably arrest the hæmorrhage is no doubt true; but it must be borne in mind that in many of these cases the hæmorrhage is not very severe, as, indeed, it is not even in some cases of complete rupture. In a case of complete rupture, however, it requires a very robust faith in the efficacy of gauze plugging as a means of arresting bleeding to enable us to believe that a gauze plug passed into a tear in the uterine wall opening into the peritoneal cavity can have much effect in arresting bleeding by making pressure on the bleeding points. It would be absurd to say that it has no effect of this kind, but that it is a certain means of arresting hæmorrhage, or one that can be relied on in the case of extensive complete tears, is a statement hard to accept. The extreme difficulty of plugging a large tear with gauze was forcibly impressed upon my mind by my experience in Case 4. The results obtained by Lobenstine by this means are exceedingly bad. Thus of his 46 cases 13 were treated by gauze-plugging alone, and of these no less than 12, or 92 per cent., died, figures which appear to eloquently demonstrate the futility of gauze-plugging in cases of complete rupture.

It is, however, quite easy to adduce figures from the literature which present much better results obtained by simple drainage or plugging, so-called conservative treatment. Thus, Eversmann collected 360 cases. Of these, 129 were treated by laparotomy, with 66 recoveries, or 59 per cent., while 78 were treated by drainage or tampons with 49 recoveries, or 63 per cent. Again, of 217 cases collected by Klein[6] 155 of the cases of complete rupture were treated by laparotomy, of whom 68 recovered, or 62 per cent., while 30 were treated conservatively, with 22 recoveries, or 73 per cent. These figures, however, refer to cases published by a large number of different observers and are therefore not of great value.

In view of the fact that different writers quote figures supporting both methods of treatment, in endeavouring to form a correct conclusion we must not rely too much upon statistics unless they include a sufficiently large series of

cases. For this reason the figures given by Petrén [7] are of considerable importance, as he has collected a series of no less than 754 cases. Analysing these figures, he finds that, of the whole, 501 were treated conservatively. These include all cases not subjected to laparotomy, and of these 140, or 28 per cent., recovered; while of the 174 cases subjected to laparotomy 82 recovered, or 47 cent., a very striking difference in favour of abdominal section.

If, in spite of these figures, we admit for the moment that gauze plugging fulfils the first two postulates and acts efficiently as a hæmostatic, while it does not increase the shock, how does it fulfil the third demand—namely, the prevention of sepsis?

The mortality from this complication has been estimated to vary between 37 and 74 per cent., and no doubt it accounts for a very large proportion of the later deaths. The best that can be said for gauze plugging is that if properly employed it forms an efficient drain, but that its efficiency as a drain is in inverse proportion to its efficiency as a hæmostatic plug. If, however, the plug is loosened after the first 24 hours, this objection is to a large extent overcome, while if an antiseptic gauze such as iodoform is used the antiseptic properties of the gauze may be of value. The main source of the sepsis, the uterus, however, is not in any way influenced, nor are the raw surfaces from which infection can occur in any way lessened by the use of a plug. On the contrary, they are rather increased in extent by efficient, and therefore tight, plugging.

We are therefore justified, I think, in concluding that while gauze plugging answers one of our postulates fairly well, it fulfils the other two certainly inefficiently, and possibly in many cases very badly.

If now we consider the usual alternative to the use of a gauze plug—namely, abdominal section or vaginal section—we are at once confronted with the difficulty that such a procedure must inevitably tend to markedly increase the degree of shock, which is already almost sufficient in many cases to kill the patient. In view of this great drawback does operative treatment present any counterbalancing advantages? To this question I suggest we may certainly give an affirmative answer.

By abdominal section—and to a lesser degree by vaginal section—we can assure the complete arrest of hæmorrhage, not only immediate but also remote; and if the uterus is removed at the same time the gravest source of danger, as far as infection is concerned, is removed, and the best possible drainage is provided for the peritoneal cavity should it be already infected. In view of these advantages it cannot be denied that if it were not for the profound shock so often present, operative treatment would probably give the best results in all cases. Indeed, judging by the cases which have been recorded of late years, operative treatment—even in spite of the fact that it increases the shock—appears to hold out the best hope for the patient, at any rate in complete tears.

Thus, Schütte [8] records 13 cases treated by operation—2 of incomplete rupture and 11 of complete rupture—with 12 recoveries. Of his series of 19 cases, 5 were hopelessly infected when first seen, and 1 was an old case, in which the child had been some weeks in the peritoneal cavity, which, however, recovered after operation.

Petrén's figures, already quoted, show the same result, and in order to avoid any error from the inclusion of small series of successful cases he has analysed the results obtained in the four large clinics of Berlin, Moscow, Budapest and Bukarest, giving a grand total of 382 cases, and he finds that of these 139, or 36 per cent., recovered—49, or 29 per cent., after conservative treatment, and 76, or 51 per cent., after laparotomy. Of a total series of 192 cases of complete rupture treated by conservative measures in these four clinics, no less than 155 died—a death rate of 81 per cent. He sums up very strongly in favour of laparotomy—at any rate, in all cases of complete rupture.

Lobenstine's figures are also striking, and are the more valuable since they are all from one hospital, and a large majority were treated by operation. Of his 46 cases, as I have already mentioned, 13 were treated by gauze plugging and only 1, or 8 per cent., recovered; 30 were treated by laparotomy, and of these 11, or 35 per cent., recovered; while 3 died undelivered.

Of 19 cases recorded by Munro Kerr,[9] 3 died unoperated upon; of 5 all incomplete tears treated by plugging 4, or 80 per cent., recovered; of 11 all complete tears treated by hysterectomy 5, or 46 per cent., recovered. I cordially agree with Dr. Munro Kerr when he says that panhysterectomy is the soundest treatment, and I would maintain that—while, for cases of incomplete ruptures, gauze plugging or gauze drainage may give very fair results—in all cases of complete rupture laparotomy and removal of the uterus, with gauze drainage of the pelvic cavity, is indicated.

This mode of treatment will undoubtedly entail a very heavy mortality; but if carried out in large numbers of cases the ultimate results will, I believe, surpass those obtained by no treatment at all, or those obtained by the use of gauze plugs if this latter method is employed in cases of complete tears.

On the whole, abdominal section would appear to be preferable to vaginal section, mainly because it enables the abdominal cavity to be more efficiently cleansed from blood and because it will enable the operator to deal more effectively with retroperitoneal hæmatomata—a point laid great stress upon by Schütte. Further than this, abdominal section enables the exact extent of the tear to be accurately defined, and by its employment hæmostasis may be more perfectly attained, and thorough drainage more certainly provided for.

If, then, we are to treat severe cases of complete tears by abdominal section, it is essential that we should take all conceivable means to lessen shock. A considerable number of cases of rupture of the uterus will certainly die from the immediate effects of the accident, but if in all cases that survive for a sufficient length of time immediate steps be taken to combat the shock, and whenever the circumstances permit abdominal section is performed as soon as possible, I believe that even better results will be obtained in the future than have been attained in the past.

For the treatment of the shock the employment of Trendelenburg's position and of warmth, the injection of pituitary extract, and, best of all, if possible, the practice of intravenous ether anæsthesia, are likely to give the best results. The last is a method of anæsthesia which is, in my experience, most useful in all cases of prolonged and severe operations likely to be accompanied by much shock, such as Wertheim's extended hysterectomy for cancer of the uterus, and in these cases of rupture it should prove most useful.

To sum up the treatment, then, of cases of rupture of the uterus as regards conservative treatment or laparotomy, I would say that while in cases of incomplete rupture gauze plugging or vaginal drainage may prove a useful method, in all cases of complete rupture the treatment most likely to give the best results in the future will prove to be abdominal section, followed by the removal of the damaged uterus and the provision of efficient drainage for the peritoneal cavity.

KING EDWARD'S HOSPITAL FUND FOR LONDON.—A meeting of the General Council of King Edward's Hospital Fund for London was held on Jan. 8th, at the offices of the Fund, 7, Walbrook, E.C. There were present: The Speaker of the House of Commons (in the chair); the Right Hon. Sir T. Vezey Strong, Bart.; the Right Hon. C. Stuart-Wortley, K.C., M.P.; the Right Hon. Sir Savile Crossley, Bart. (honorary secretary); Sir Henry Burdett, Sir Horace Marshall, Sir John Craggs, Dr. Edwin Freshfield, and Mr. John G. Griffiths (honorary secretary). The Speaker announced that the Governors had appointed the Rev. R. F. Horton, D.D., as a member of the General Council in place of the late Rev. J. Guinness Rogers, D.D. The order of appointment, signed by the Governors, of the members of the General Council, members of committees, and officers for the year 1912 was read. The resolutions providing for the work of the Fund for 1912, which were approved at a meeting of the Governors and General Council held at St. James's Palace on Dec. 11th, 1911, were formally adopted.

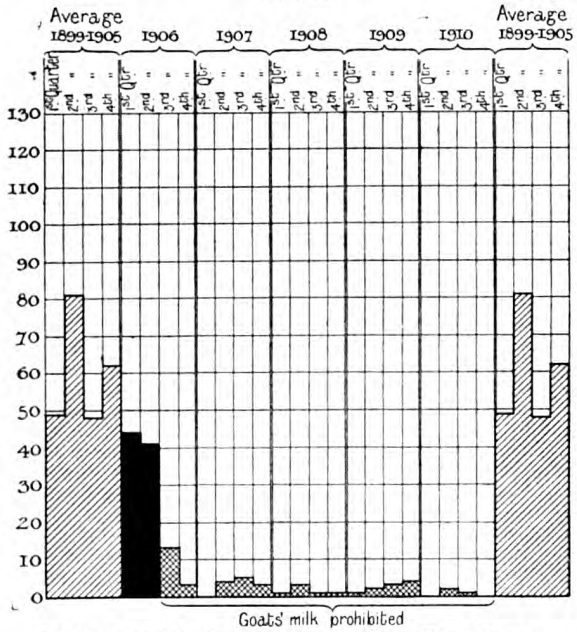
THE INCIDENCE OF MEDITERRANEAN FEVER IN MALTA AND ITS RELATIONSHIP TO THE SIZE OF THE GOAT POPULATION.

BY J. W. H. EYRE, M.D., M.S. DURH., &C.,
HUNTERIAN PROFESSOR AND EXAMINER IN BACTERIOLOGY, ROYAL COLLEGE OF SURGEONS OF ENGLAND; DIRECTOR, BACTERIOLOGICAL DEPARTMENT, AND BACTERIOLOGIST, GUY'S HOSPITAL, ETC.

COINCIDENT with the adoption in 1906 of the recommendation of the Mediterranean Fever Commission that the use of milk from the Maltese goat should be prohibited, a striking diminution occurred in the case-incidence of Mediterranean fever upon the naval and military forces stationed at Malta.

The absolute prohibition of goats' milk as an article of diet took effect in the services from the beginning of June, 1906. The average case-incidence of Mediterranean fever in the navy for the first six months of the year is 130, and for the second half of the year 110. The actual case-incidence in 1906 was 89 for the first of these periods (during which attempts at milk sterilisation had been made at the Naval Hospital) and 16 for the second period, or a total of 105 instead of 240 (see Fig. 1). In 1907 12 cases were notified;

FIG. 1.

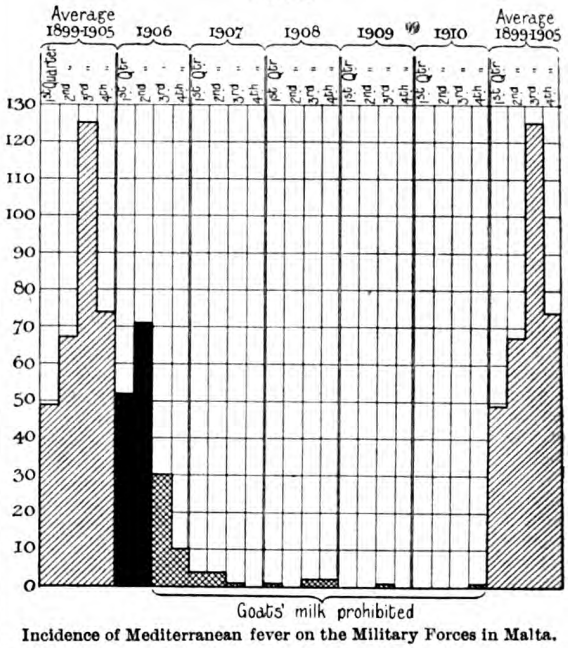


Incidence of Mediterranean fever on the Naval Forces stationed at Malta. Note that the average incidence for each quarter appears at the left of the diagram and is repeated at the extreme right. The same arrangement has been followed in Figs. 2 and 3.

in 1908, 6 cases; in 1909, 10 cases; and in 1910, 3 cases. So that it would appear that, instead of the navy having to deal with some 240 cases of the disease each year, less than 10 men become infected, a reduction of more than 95 per cent., and a reduction, moreover, which took place abruptly on the discontinuance of the use of an infective food. I suppose that in the circumstances it would be too much to expect that the disease would entirely disappear from the Mediterranean Fleet, since we know that *M. melitensis* septicæmia is endemic throughout the whole of the Mediterranean littoral, and indeed in all those tropical or subtropical countries where the goat is the sole or principal source of the milk-supply; and the bluejacket, although careful enough to avoid milk whilst upon the island of Malta, is by no means equally careful when ashore at other Mediterranean ports. Moreover, some of the cases recorded in the naval statistics occur amongst the native bandsmen and mess attendants employed on warships and have probably resulted from contact with infective material in their own homes whilst on shore leave.

In the army the case-incidence was slightly above the average in the early months of 1906, but it dropped rapidly after the introduction of the prohibition order, so that in the third quarter of 1906 there were only 30 cases, as compared with an average of 125; and in the last quarter there were only 10 cases, against an average of 74 (see Fig. 2). In 1907

FIG. 2.



Incidence of Mediterranean fever on the Military Forces in Malta.

the total for the year was 9 cases, instead of an average of 315. In 1908 5 cases were notified; in 1909, 1 case; and in 1910, 1 case. Here we appear to have an irreducible minimum in a body of troops living in the island in the midst of so much infective material.

This diminution in the case-incidence of Mediterranean fever which took place after the removal of an infective item from the dietary of the sailors and soldiers is regarded by some to be merely *post hoc*, and the evidence adduced by the Mediterranean Fever Commission as to the infectivity of goats' milk, and indeed as to the causal association of *Micrococcus melitensis* with Mediterranean fever, is ignored, derided, or denied. With this type of argument the impartial critic can have but little sympathy, and I do not propose to do more than refer to it. But in certain quarters the assertion has been made, and frequently repeated, that the diminution in the case incidence in the garrison, naval and military, of Malta is merely the result that one would expect to follow upon improved sanitary conditions generally, and is in no way dependent upon, or even associated with, the prohibition of the use of goats' milk—even if such milk is assumed to be infective. The removal of a small portion of the military garrison to modern barracks is instanced as of the first importance. The fallacy of this argument is shown in the following table, giving the age of some of the barracks and the incidence of Mediterranean fever therein for the six

Built.	Barracks.	Case-incidence in 1906.

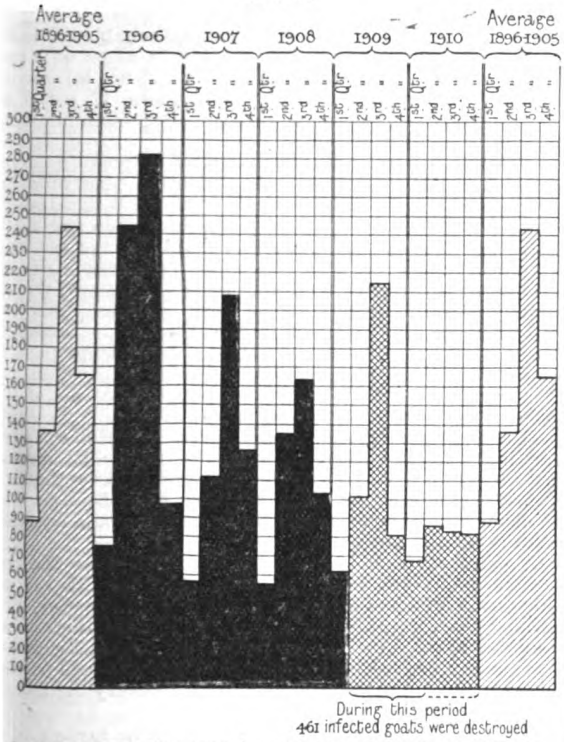
months before (January–June, 1906) and the six months after (July–December, 1906) the issue of the prohibition order.

Again, improved sanitary conditions can scarcely be urged in support of this contention so far as concerns the navy, for neither the naval hospital at Bighi nor the construction of warships, from the sanitary point of view, has undergone any change in the last five years. In fact, the only sanitary improvement of any importance that has taken place in Malta during the past four years is the reduction in the goat population of the island, a point to which reference is made later.

Finally, consideration of the figures representing the case incidence upon the civil population fully confirms the finding of the Mediterranean Fever Commission (see Fig. 3). The

FIG. 3.



Incidence of Mediterranean fever on the civil population of Malta.

number of cases notified during the first three months of 1906 was slightly lower than the average for the corresponding period. At the commencement of the second quarter of the year the goatherds commenced to get uneasy concerning what they believed to be a libel upon the animals that provided them with a livelihood. Towards the middle of the second quarter they chose to consider themselves affronted by the desire of the Fever Commission and the public health authorities to analyse specimens of the milk offered for sale, and they went on strike (shortly before the issue of the prohibition order), and refused to supply the contract quantities to the naval and military authorities, with the result that a large quantity of highly infective material remained upon their hands.

I have already pointed out that in the ordinary way the Maltese goatherd does not drink the milk from his goats: he simply keeps the goat in order to sell the milk. But now, during this period and the following three months, when he had so much milk on his hands and so little money to purchase other provender, he was compelled to use the food ready to his hand for himself and his family, with the result that 526 cases of the disease were notified during the second and third quarters, instead of an average or 379, and a total for the year of practically 700 cases, as against the average of 632. Naturally, many of the milch goats were sacrificed—in other words, slaughtered and sold. Others, with the incidence of hard times and consequent lack of food, became dry, and in the following year, 1907, 502 cases only were notified for the whole year as against the average of 632. By the following year (1908) many well-to-do Maltese families had taken to heart the advice with regard to goats' milk that the public health department of the island had so constantly reiterated, and were either drinking imported condensed milk, or were boiling the supplies of goats' milk obtained locally, and a further small reduction in case incidence to 456 was noted in 1908, accompanied in accordance with the law of supply and demand by a consequent further reduction in the number of milch goats in the island. By 1909 the public health authorities of Malta had obtained additional powers with regard to the purification of the milk supplies, and from the beginning of the second quarter of 1909 up to the end of March, 1910, no less than 461 milch goats in whose milk the micrococcus melitensis had been detected were bought in by the health authorities and destroyed. The result of the removal of so much infective material from the island becomes apparent in the incidence of the disease during the year 1910 (included in the dotted extension of the bracket in Fig. 3), 318 cases only being notified, as compared with the average of 632. The plea that this reduction in the case of the civil population of Malta is due to improved sanitation cannot apply here. Speaking generally, the sanitation of Malta was as good six or eight years ago as it is now, and the only striking improvement in recent years has been the reduction of the goat population of Malta from *17,110* in 1907 to *7619* in 1910; in other words, the removal of infected goats and the consequent reduction in what I conceive to be the main causative factor in the production of the disease.

Guy's Hospital, S.E.

ELECTRIC METALLIC COLLOIDS AND THEIR THERAPEUTICAL APPLICATIONS.

BY B. G. DUHAMEL, M.D.,
OF THE FACULTY OF MEDICINE OF PARIS.

THE introduction of the metallic colloids into medicine constitutes a new departure in therapeutics the significance of which does not appear as yet to be generally recognised. Under these circumstances a brief review of the physical qualities, physiological properties, and therapeutical effects of these remarkable bodies presents a certain practical interest.

A colloid is usually defined to be a substance that will not pass through an animal membrane, of which gelatin, albumin, and dextrine are typical instances. Until recently, indeed, this was about all that was known of them, although, as the animal organism is wholly composed of colloids, it is only by a thorough knowledge of their interaction that the reactions taking place in the human organism can be understood.

The discovery that it is possible to convert certain metals and metallic salts into the colloid state and the careful study of these metallic colloids, however, show that they are reduced to infinitely small particles, so small as to be visible only by the aid of the ultra-microscope. Some idea of the minuteness of these particles can be gathered from the fact that a cubic millimetre of ordinary colloidal gold is estimated to contain 1,000,000,000 of them, and what would be considered a solution of *fine* particles at least twice that number. These particles or granules are animated by what is known as Brownian movement and are enabled to remain in suspension in a liquid medium almost indefinitely, their stability depending on the size of the granules, the nature of the body and of the vehicle employed. It is interesting to note *en passant* that the number of granules varies according to the cube of their size, so that if their size be reduced to one-half their number is multiplied by eight, a fact of considerable practical importance because the activity of these solutions depends upon the multiplication of these centres of activity.

There are two principal ways of producing metallic colloids—viz., chemical and physical (electrical). The *chemical* preparation of a colloid metal is effected by the slow reduction of a salt of the metal, as, for instance, by

treating nitrate of silver with a mixture of sulphate of iron and citrate of soda. The *physical* method consists in passing the electric arc between electrodes of the metal to be converted into colloid, plunged into distilled water. Under these conditions the electrodes throw off an extremely fine powder which remains suspended in the liquid. The two methods of production yield widely different results, and from a therapeutical point of view I need only deal with the electric colloid metals, since these only present the necessary homogeneity, minuteness of granules, purity, and stability.

A solution of electric colloid silver (small-grained) is of a brownish-red colour (the solution with larger grains has a green tinge). It diffuses light and is vaguely opalescent. For therapeutical purposes it is made stable by modifying the composition of the aqueous medium and is rendered isotonic with blood serum by the addition of sea-salt. Thus prepared for use it is known as electrargol and is one of a series, electraural, electroplatinol, electromercurol, &c., which all appear to possess the same properties in approximately the same degree, a fact which militates in favour of the view that it is the physical state of the substance rather than its nature that determines its effects. These colloid metals, like colloids in general, have a special electric charge, and thanks to their state of fine division they possess a certain catalytic power—that is to say, by their mere presence they can determine very powerful chemical action out of all proportion with the quantity of matter brought to bear. From this point of view the action of colloids resembles that of the ferments.

When colloids are mixed together they form complexes possessing the properties of the bodies originally brought into contact. It is to the affinity of the colloids for each other that we must look for an explanation of the actions of toxins and antitoxins, the phenomena of agglutination, and, indeed, most of the recently elucidated biological phenomena. Since the organism is a complex agglomeration of colloids we have everything to gain by introducing medicinal substances in the colloidal state; indeed, the action of the colloid metals, both locally and constitutionally, testifies to an extraordinary bactericidal, anti-infective energy, both directly and by reinforcing the organic defences.

Therapeutical Applications.

Although of comparatively recent introduction the therapeutical applications of the colloid metals are numerous and interesting; indeed, their employment inaugurates a fresh chapter in therapeutics which is daily being added to.

Speaking generally, the colloidal metals are especially remarkable for their inhibitive action in infective states—septicæmia and pyæmia. This action has been shown to be due to their stimulating influence on phagocytosis and to their destructive effects on micro-organisms and their toxins as shown by the immediate fall of temperature and the subsidence of the constitutional symptoms of intoxication. They are employed as a rule for the sake of their constitutional effects, for which purpose an injection of from 5 to 20 c.c. is made into muscle or, in urgent cases, into the veins. It is worthy of note, however, that in presence of a local infective lesion, such as epididymitis, bubo, mammary abscess, &c., valuable effects are obtained by making one or more injections into the affected tissues or as near thereto as circumstances permit, in addition to the constitutional treatment. Similarly, the colloid products can be injected, in accordance with the indications, into the spinal canal (cerebro-spinal meningitis) and the serous cavities (pleurisy, empyema, &c.) or applied locally to the surface of diseased mucous membranes. Their introduction into the circulation is followed in a few hours by a sharp febrile reaction for which we must be prepared, but which soon gives place to a marked and durable fall of temperature associated with remission of the general and local symptoms. If treatment be postponed until the patient is *in extremis* this reaction may be wanting.

The colloidal metals have been extensively employed in acute inflammatory infections of the lungs (pneumonia and broncho-pneumonia) and pleura (pleurisy and empyema). The injection is followed by a marked change in the opsonic index (positive) and the crisis in pneumonia is notably precipitated. It is indeed in the treatment of inflammatory affections of the lung and pleura (and in puerperal fever, *vide infra*) that the electric colloids have yielded the most brilliant results, as will be seen on reference to the original papers. In addition to the intravenous or intramuscular injections, electrargol has been introduced into the pleural cavity in presence of pleurisy and empyema, apparently with much benefit.

In puerperal septicæmia (puerperal fever) and peritonitis, whether consecutive to labour or as the result of appendicitis, the most remarkable effects follow the intravenous injection of these colloids; indeed, in some instances the patients have been rescued from apparently inevitable death. It is obviously undesirable to postpone intervention until the disease has reached a stage at which the organism has become irresponsive to treatment of any kind. We know that this is the case when the reactional rise of temperature does not take place, and clinical experience shows that patients who fail to react do not as a rule derive benefit from the treatment.

Even more interesting are the results obtained in acute meningitis and in epidemic cerebro-spinal meningitis. In the latter electrargol can be employed either alone or in conjunction with the serum treatment. The injection is usually intravenous, but in severe cases it should be made directly into the spinal canal so as to obtain immediate effects.

Without attempting to exhaust the list of possible applications of the colloid metals, I may mention that within the last two years they have been employed with signal success in the treatment of acute epididymitis. This painful and disabling affection can often be nipped in the bud by a timely injection of 1 or 2 c.c. of electrargol *into the epididymis;* even when the disease is fully developed the pain usually subsides within a few hours of the epididymal injection, and the duration of the disease is thenceforth measured by days instead of weeks. Their employment in acute urethritis is being investigated and it is claimed that they abort or avert the principal complications of this redoubtable though common affection.

It will be seen that the action of the metallic colloids is not limited to any particular variety of microbial infection, but extends to most. In typhoid and typhus fever they exert the same anti-infective action and they have been employed in diseases as far apart as Mediterranean fever and erysipelas, cystitis and tonsillitis.

A glance at the bibliographical notes will show that these remarkable results have not been obtained by any one observer or group of observers, nor in any one country. They are daily being placed on record in medical literature all over the world. In view of their daily increasing field of usefulness it can hardly be doubted that a new and interesting chapter has been opened up in contemporary therapeutics by the introduction of the colloid metals.

One point stands out prominently, and that is the absolute innocuousness of these bodies, whether injected into the veins or muscles or into the spinal canal. Injected into muscle they cause very little local reaction or pain, and the dose is determined solely by the requirements of the case since they are devoid of toxicity. No hesitation need be felt in applying this treatment to children in doses of from 3 to 5 c.c., according to age. It is unnecessary to add that the injections are to be made with the usual antiseptic precautions.

Paris.

OBSERVATIONS UPON THE TREATMENT OF GONORRHŒAL CONJUNCTIVITIS IN THE ADULT.

BY J. STROUD HOSFORD, F.R.C.S. EDIN.,
ASSISTANT SURGEON, ROYAL EYE HOSPITAL, SOUTHWARK; ASSISTANT OPHTHALMIC SURGEON, LONDON TEMPERANCE HOSPITAL;
AND
G. BROOKSBANK JAMES, F.R.C.S. ENG.,
SURGEON, ROYAL EYE HOSPITAL, SOUTHWARK; AND ASSISTANT OPHTHALMIC SURGEON, WESTMINSTER HOSPITAL.

WE have observed, in common with most ophthalmic surgeons who have given attention to this subject, that gonorrhœal conjunctivitis in the adult is in all cases after the age of 30 attended with most disastrous results to the eye. Not only is all useful vision in these unfortunate cases completely lost, but the damaged and shrunken globe not infrequently remains a distressing and unsightly object in the orbit. We believe that this untoward result is not only unnecessary but preventable if the patient is seen early and appropriately treated. The involvement of the cornea constitutes the great danger in this affection.

1. It may slough wholly from strangulation owing to the pressure of the brawny lids and the gelatinous chemotic swelling round its margin.

2. Its epithelium may be readily abraded and a site exposed for the ingress of the terrible gonococcus by even the gentle manipulations of a skilled attendant.

3. The digestive powers of the toxic products contained in the discharge have a most deleterious influence on the vitality of the structures of the cornea.

4. To these must be added what we have come to consider as the almost uniformly pernicious influence of the caustics and astringents applied in the early stages of the disease. We refer more particularly to silver nitrate, protargol, argyrol, and perchloride of mercury. These, by the reaction they cause, lead to greater constriction and chemosis, whilst they merely remove the superficial layers, leaving the deeper structures of the conjunctiva untouched. Moreover, the renewal of these applications is not only distressing and exhausting to the patient, but is attended with positive danger to the cornea. Further, this method of treatment is, even in favourable circumstances, a lengthy one, the conjunctiva being left in an irritable, and occasionally papillomatous, condition for many weeks, while recurring ulcerations of the cornea are much to be feared.

It has always appeared to us that this treatment would be justly condemned if adopted by any modern surgeon in urethral gonorrhœa, and that it is essentially unscientific and unpractical. For some years we have adopted the following method in dealing with these very serious cases and with the most uniformly gratifying results. The early symptoms of this disease may be recognised, or at least strongly suspected, by the practised eye even before a culture has been obtained, though this should never be omitted.

Treatment.

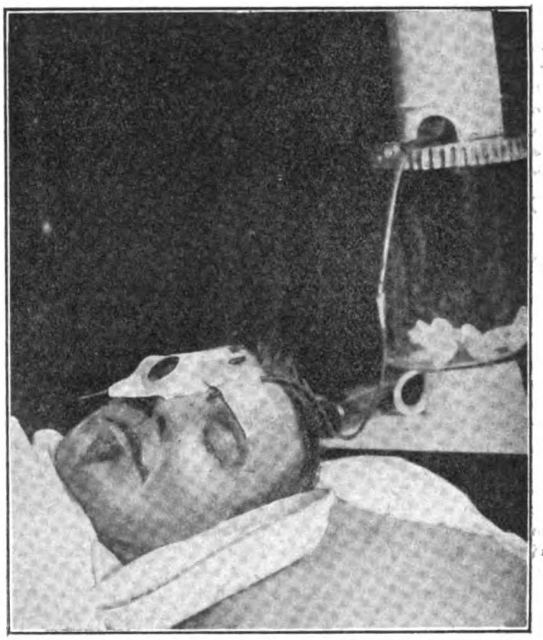
1. The patient should at once be placed in bed and remain there until all danger is passed.

2. A low diet should be prescribed, consisting of milk, barley water, eggs, fish, toast and butter, weak tea, &c., for the first ten days. The bowels should be kept freely open with mercury and saline purges, and aspirin (gr. x. thrice daily) and quinine bisulphate (gr. ii. thrice daily) are probably the best internal remedies to administer in this disease.

Local Treatment.

With regard to this all-important question we have found that the constant use of the douche is the primary curative factor. It may be applied either by a mechanical apparatus fastened to the head or by the hands of a relay of properly instructed nurses. These should sit behind the patient's head and apply the unintermitting stream as the surgeon may direct from time to time. No cessation in the flow is to be permitted for a moment either day or night. The solution which we have found most satisfactory for this purpose is one of permanganate of potash, varying in the early stages from 1 in 15,000 to 1 in 20,000, and in the later stages a solution of boric acid, gr. viii. ad ℥i., may replace this and is all that is necessary. The temperature should be from 85° to 90° F. in the can, where a thermometer is constantly present. We do not use any ointment either within the conjunctival sac or on the surrounding skin, as it tends to interfere with the proper application of the solution. When possible the patient should be encouraged to open his eyes slightly every ten minutes. No manipulation of the lids except by the surgeon should be permitted.

In the arrangement of the douche the can should be placed not higher than one foot above the patient's head. (See figure.) The end of the fine rubber tube leading from it should be either fixed by plaster or held at the naso-orbital margin, and the stream allowed to trickle constantly across the palpebral fissure, which it will be found that there is a tendency for it to do if properly adjusted. If a slight coating forms along the lashes it can be removed readily by a warm solution of sodii bicarb., gr. x. ad ℥i., the lashes being gently stroked downwards. For the first four days, provided that the sequelæ to which we shall refer later do not call for further examination, only the gentlest attempts should be made to



expose and inspect the eye. After this time, as the swelling is in all probability subsiding, the cornea should be carefully examined for minute specks, and signs of iritis or hæmorrhages into the anterior chamber should be looked for. The patient should be encouraged to open the lids himself, the surgeon merely assisting by the gentlest manipulation of the upper lid. It will be observed in the severer cases that the chemosis in itself tends to keep the lids apart, or at least prevents firm closure, and that the portion thus exposed and submitted to the stream of fluid includes that part of the cornea—i.e., the lower limbus—most susceptible to damage from the toxic inflammatory products.

If the disease is diagnosed in the first days and irrigation is at once adopted a surprising improvement will be seen in the course of the next four days, and the surgeon may be tempted to relax the continuous douche. Relapse is, however, much to be feared if the treatment is not continued for the next three or four days. It may be pointed out also that even in the neglected cases, where the patient is seen by a specialist at a dangerously late stage, eight days' continuous irrigation will be found sufficient to bring the case completely under control, provided the cornea is not affected when the surgeon is called in.

Complications and Sequelæ.

Lids.—A malignant form of the disease, where the lids become almost black and show signs of venous stasis and even threatened gangrene. In this condition the outer canthus should be freely incised, and, if necessary, its edges

sewn apart. There is no danger of orbital cellulitis ensuing if the continuous douche is persisted with. These cases are, however, rare if the disease has been early recognised and the irrigation treatment adopted.

Cornea.—If the douche is discontinued at too early a stage we have found that corneal complications are apt to appear as grey spots at the limbus or in the centre of the cornea. A renewal of the irrigation has led to rapid arrest of further trouble. Even if a definite ulcer appeared, which we have not seen under this method of treatment, we should continue to persevere with the douche and not resort to the more heroic measures of the cautery or the silver compounds. A slight vascularity of the upper corneal limbus should not excite apprehension. There is no tendency for ulceration to occur in this situation; it occurs in the centre from devitalisation, or at the lower part from contact of the secretion, or from exposure. We have not found it necessary to make radiating incisions into the chemosed tissue since adopting this method of treatment. The subsidence of the chemosis may be assisted after the tenth day, when the discharge has mostly ceased, by painting the conjunctiva of the lower lid only with gr. ii. ad ℥ i. of silver nitrate or the use of permanganate of zinc drops, gr. 1/8 ad ℥ i. The globe and upper lid should not be touched by these astringents. The eyeball is always tender on the slightest pressure during the first fortnight, and the eye is hypersensitive to light even through the lids. There is, however, but little true tendency to iritis at this stage under this treatment, but it is our practice to instil atropine solution every other day, gr. ii. ad ℥ i., after the eighth day for the general comfort of the patient. We have not found as sequelæ after this method of treatment papillary roughness of the conjunctiva, obliteration of the fornices, &c.—results by no means uncommon after the astringent and caustic methods of treatment usually adopted. Neither have we encountered such terrible results as orbital cellulitis, meningitis, &c.

It must be remembered that however well the eye may have recovered in certain cases the patient may suffer at a later stage from rheumatic troubles affecting the periarticular tissues and serous membranes. These occur chiefly in the urethral cases at about the fourth week, when the patient is up and about and scleritis may supervene at this period and ultimately cause staphylomata. We have, however, never met with this complication after the irrigation method. It points to the importance of carrying out suitable treatment for the urethral complications, to warm clothing and careful dieting, and the avoidance of anything which may expose the patient to cold and damp. Abstention from alcohol and tobacco and a diet consisting chiefly of milk and farinaceous food are indicated until the patient has completely recovered.

In the early stage the patient will naturally suffer somewhat from insomnia, owing to the want of rest which this treatment involves, but this should not prevent the surgeon from persisting with the douche, the issue being so vital. It is most important that the stream should trickle uninterruptedly and not fall by drops upon the eye, for it is then apt to produce a peculiar mental irritability. Veronal, gr. viii., in tea can be given at night, but a fair amount of rest is really obtained. The light of the room should be subdued, the sound eye protected by a Buller's shield well aerated above and below, which should not be removed unless absolutely necessary. The nurses should wear protecting gloves of indiarubber. All woollen swabs should be destroyed by burning. The fluid is collected by means of towels and mackintoshes, the towels being boiled, dried at the room fire, and used again. The room should be well aired and kept at a temperature of 65° F. The risk of infection to the attendants should be pointed out.

With regard to vaccine-therapy we have not satisfied ourselves of its efficacy, but we believe that the use of anti-streptococcic serum by the rectum is of service in the rheumatic complications which may arise.

HOSPITAL FOR SICK CHILDREN, GREAT ORMOND-STREET, LONDON.—The weekly demonstrations and lectures at this hospital have recommenced. These lectures are open free to all medical practitioners. The next lecture will be given on Jan. 18th, at 4 P.M., by Mr. E. M. Corner who will take as his subject Delayed Chloroform Poisoning.

PSYCHOTHERAPY AND GENERAL MEDICINE.

BY WILLIAM P. S. BRANSON, M.D. CANTAB., M.R.C.P. LOND.,

ASSISTANT PHYSICIAN, ROYAL FREE HOSPITAL; LATE ASSISTANT PHYSICIAN, EAST LONDON HOSPITAL.

I.—*Retrospect and Introduction.*

THE principle that mental impressions can influence bodily function has long since met with almost universal acceptance, and has been crystallised from time to time into a great variety of cults which have had their vogue and passed, or at the best survive as more or less local and sporadic fanaticisms. Our profession, with the rest of the world, has admitted the truth of the principle, but furtively or with an air of easy tolerance, as though it had no bearing on the problems set by sickness. The object of this paper is to submit that the profession cannot afford to continue in this attitude of detachment, while the furtiveness of such interest as is shown in the matter becomes readily intelligible upon a brief retrospect. Until the early years of the seventeenth century the science of medicine was the paradise of theorists. Then came the awakening, and during the succeeding centuries men witnessed an almost unceasing flow of important discoveries emanating from exact observations, post-mortem dissections, and the like. It is no wonder that the best minds in the profession were monopolised by strict materialism when they compared its harvest with that of the unchastened theorising which had held sway so long. In consequence the more nebulous regions of medicine, where mind and body meet most intimately, became—or perhaps one should rather say remained—the happy hunting-ground of impostors and charlatans, of Mesmers and Cagliostros; and the evil odour which clung to them when these worthies had come and gone left decent people less than ever inclined to risk their reputations in such doubtful company. So things went on till Braid, in the middle of the last century, took Mesmer's animal magnetism in hand, showed that it had nothing to do with magnetism, and did a great deal to place its manifestations on a scientific footing. Presently Charcot himself was persuaded, took up the practice of hypnotism, and made it temporarily orthodox. Soon, however, the scene of his labours became a by-word for functional manifestations of a degree never seen elsewhere, and the whole business sank again into a disrepute the deeper for its temporary emergence under such distinguished patronage. Yet in spite of the shady and undulating career of the methods by which men have tried formally to employ the mind as a therapeutic path, the fact of its usefulness in suitable cases remained unshaken and has continued to be applied in various ways. One of these is called "psychotherapy," and it is with a variant of this that I propose to deal. Amongst other offspring of the same stock which are still active may be mentioned "Christian Science" and Freud's psycho-analytical method of treating hysteria.

I suppose there are few young practitioners who have not had to puzzle their heads over the paradoxical things seen in the out-patient room: over the efficacy of gentian and rhubarb in the case of A, while in the case of B, whose affection seems identical, the draught shows no virtue of any kind. Being no exception to the rule, these and such discrepancies prompted me to keep my eyes open for help from someone of larger experience; but, whether through ill-luck or because the subject did not appeal to those to whom I looked for guidance, I continued to flounder along by myself until I made the acquaintance, through a book by Professor Dubois, of Berne,[1] of a method of practice called "rational psychotherapy." I knew, of course, that in the large family to which it belonged there had been several notorious members; but being unwilling to condemn them all because some had led so-so lives, and finding in the method much that appealed to me as reasonable, helpful, and explanatory of my difficulties, I began to exercise its precepts as well as I could some five or six years ago. Sufficient time has now elapsed for me to say that it can be invaluable sometimes, and often of considerable assistance.

[1] The Psychic Treatment of Nervous Disorders, American translation, Funk and Wagnalls Co., 1905.

So I imagine it may interest those who have not anticipated me if I give a slight sketch of what rational psychotherapy implies, of its virtues and limitations as they present themselves to me, and of the way to put it into practice. I ought perhaps to say that Dubois is beyond me as regards portions of his theory, especially its metaphysics, and that I have been a good deal less successful than my first reading of the book led me to hope. But I am persuaded that a knowledge of his principles is a great help in dealing with "nervous" people, under which heading may be included the bulk of people who have been out of health for any length of time, whatever they may be when well.

I must premise that no one need expect any success with this method who does not believe, without mental reservation, that a man may be genuinely ill even though he has no inflammation, tumour, fracture, or indeed any pronounced objective loss of physical or mental health. The practitioner must also have or achieve some degree of intuition as to what is at the back of a patient's mind, for the emotional states which underlie neurotic manifestations are often well concealed by the victims of them, whether from fear, or a dislike of being laughed at, or some more complex emotional stimulus, and the penetration of this disguise is a condition of success in treatment. He must have, too, a ready and persuasive tongue, a convincing air of optimism, and unwearying patience. Lastly, he needs a good supply of human kindness, and, most important of all, a capacity to let it appear on the surface; and this last is no easy accomplishment for English reserve.

Theoretically the method is based upon the following propositions. 1. That ideas, through the emotional states to which they give rise, are capable of disordering bodily function. 2. That disorders of function, on their part, are capable of evoking ideas and depressed emotional states which, in obedience to the first proposition, end by disordering function still further. 3. That in so far as a disease is ideogenic it ought to be treated on psychical lines—that is, by discharging the pathogenic idea. 4. That though pathogenic ideas can be discharged by an appeal to the imagination, it is better to discharge them by an appeal to the reason, for the former method tends to confirm imaginative and irrational leanings, while the latter tends to correct them.

These propositions are fundamental, and must therefore be established even at the risk of being tedious.

1. It is well known that a number of functions, partly reflex and partly under ordinary circumstances voluntary, can be inhibited by over-anxiety as to their performance. For instance, everyone is familiar with the difficulty experienced by some people in passing urine in the doctor's presence. Again, I once saw a man enter a room full of undergraduates and, producing a snuff-box, offer to bet half-a-crown that no one present could make himself sneeze within five minutes. The challenge was accepted freely, and a number of people plied themselves liberally with snuff—so liberally that they sneezed immoderately for some time afterwards; yet no one succeeded in performing the feat within the allotted time, anxiety for its accomplishment having inhibited the natural reflex. Conversely, a different form of emotion may have a precisely opposite effect. Thus the curious mixture of expectation, hope, and fear which is prone to attack those about to perform in public—the "needle" of the rowing man, the "stage-fright" of the platform speaker—is marked not only by polyuria but by frequency of micturition out of proportion even with the enlarged volume of urine; while when the emotion is pronounced a "nervous diarrhœa" is common enough during the half hour immediately preceding the trial. These events are evidence of variations in the irritability of the controlling centres at the instance of varying emotions. They will suffice to bear out the statement that emotional states can disorder function, though they could be multiplied without difficulty from the natural history of everyday life.

2. The converse proposition that emotional conditions are influenced by bodily states hardly needs to be laboured, but the proposition calls for some comment. It is a commonplace that a man's temperament in sickness is other, and generally less buoyant, than it is in health. This is not necessarily because the disturbance of function is itself to blame, but because its existence induces a superstructure of depressing emotions—apprehension, self-pity, vexation, and so forth—a superstructure varying interminably with the temperamental endowments of the invalid. Therefore it is that in one man a disturbance of function in itself trivial produces only trivial effects, while in another a disturbance intrinsically no greater than the first evokes a stream of secondary emotional effects of such consequence that they in their turn become capable of disordering function; and thus a reciprocating series is begun which not seldom leads the patient into pronounced and chronic invalidism. A hypothetical example will, perhaps, make this matter clearer than an abstract statement. Two healthy men, A and B, become equally and scandalously drunk one night at a respectable gathering, and both on the following day are paying the penalty in the shape, amongst others, of disordered gastric function. A is equable, phlegmatic, unimaginative. He surrenders himself to the inevitable, laughs off his lapse in good manners, starves himself for a day, and is well again. B is less stable, more sensitive, morbid, if you please. To his physical discomforts are added scruples of conscience, disgust at the way he has compromised his good name in his cups, and a general tendency to be seriously upset about his escapade. He thus passes easily into a pessimistic frame of mind well adapted to introspection and a tender care for the sensations arising from his outraged stomach. By dint of unremitting attention to his tongue and epigastrium he becomes satisfied presently that his rash indulgence has damaged his economy to some purpose, and in the course of five or six weeks is the perfect picture of a "nervous dyspeptic." By this time, of course, he is genuinely ill, for the gloom that oppresses him does not admit of any healthy digestion of food, while his strained attention does not miss a single sensation arising from his alimentary canal. In short, the reciprocating series I have mentioned has him fully in its grip, and his illness, though initiated by a physical disorder, is now far from physical in essence. In order to round off the fable and to point the moral, it may be permitted to invent a not unlikely future for this man. He now consults a doctor. If the latter be one of those who have no eyes or interest for anything but organic lesions, the patient leaves the consulting-room confirmed in his apprehensions. He has, let us say, a dilated stomach. He takes with him a list of forbidden articles of food, together with precise directions as to the eating of the few that are allowed him. He will next be found receiving lavage from a gastric specialist, and with some temporary benefit. Finally, after a series of relapses he may find partial salvation in a proprietary pill or electric belt, or he may visit a surgeon who by dint of gastro-enterostomy (i.e., suggestion), combined with rest and feeding (enforced by the operation), restores him to health until such time as his fancy shall renew its tricks upon him. This may be thought an overdrawn picture, but it is not. I have authentic knowledge of a lady who underwent six major operations for the relief of obscure abdominal symptoms, and was finally cured by a vaccine.

3 and 4. Assuming as self-evident the third proposition that in so far as a disease is ideogenic it should be treated psychically, it is necessary to say a few words concerning the choice of means for this end. Pathogenic ideas can be discharged, if at all, in one of two ways; either by an appeal to the imagination or by an appeal to the reason. The appeal to the imagination is the method of animal magnetism, of hypnotism, and of all forms of bald suggestion. It is pure chicanery (not that it may not be admissible in certain instances), and though its immediate effects are often beneficial *ad hoc* it does nothing to correct the underlying mental state, but rather, one might suspect, confirms it in its imaginative and irrational leanings. Rational psychotherapy, on the other hand, attempts to discharge the pathogenic notion by an appeal to the reason. It argues that pathogenic ideas exercise their harmful effects by virtue of apprehensive self-suggestions and the depressing emotional states produced by them; that these self-suggestions are generally unjustified by the facts, being the product sometimes of false premisses due to ignorance of physiology, or to rash conclusions prompted by alarm. If, therefore, the best is to be done for the patient, not only must the existing harmful idea be dismissed by attempting to explain the genesis of the disorder along rational lines, but the patient must be brought to understand the mechanism which has entrapped him in order that he may be on his guard in future. That is to say, he is not to be considered cured until he has been brought to realise how much his body is at

the mercy of his mind, and how vital it is to his future welfare that he should be more critical in his acceptance and interpretation of his sensations. So the method endeavours to follow out the chain of events which has evoked the harmful notion, to identify the physical basis, if there is one, and to separate it from the superstructure of self-suggestion which is often disproportionately developed, in order that each element may be dealt with on its merits. The former is then attacked by physical means, the latter by explanatory and reassuring conversation.

II.—*Some Definitions and Postulates.*

I now wish to submit a few further psychological considerations of importance. This may seem a fine description of the string of platitudes which follows, and if I cite them with a solemn air it is not from ignorance that they are platitudes, but because they seem to me to be overmuch forgotten in dealings with sick humanity. But first it is necessary to define the meaning which will be attached to two words of frequent occurrence in the sequel, for they are often vaguely employed in medical literature—viz., "neurotic" and "functional."

A *neurotic person* is here held to signify one who reacts with undue violence to a stimulus of given intensity, and nothing more. This exaggerated responsiveness is inherent in some people, while others who are usually of average balance may be made temporarily neurotic by circumstances. The term does not necessarily connote the lack of judgment which is characteristic of the hysterical person, though the latter is often neurotic; nor has the neurotic constitution in itself any sinister significance (beyond the nuisance of it to its possessor) provided that it be coupled with a critical and judicial mind. But undoubtedly the delicacy of the whole apparatus, which is a cardinal feature of the neurotic habit, does lead to an enhancement of the emotional and imaginative faculties, and the more these are enhanced the more need is there that they should be under the governance of the reason. It is only in so far as this critical control is lacking that the neurotic person tends to become hysterical. I imagine that Shakespeare must have been an example of the best neurotic type, combining in an extraordinary degree emotional and imaginative activity with judgment. Nelson, on the other hand, had far less balance, and academically considered, belongs to the commoner order of genius in which judgment readily goes by the board as soon as the emotions become engaged. It seems to me very important on medical grounds to recognise that the neurotic habit does not necessarily imply defective judgment. For the neurotic constitution cannot be altered unless it has been developed in response to circumstances, but a great deal can be done to call judgment into play so long as capacity for exercising it exists; and this is the basis of the therapeutical bearing of the subject before us.

A *functional disturbance* will be taken to mean a disturbance of function however arising—that is to say, the term will not carry any veiled significance indicative of a neurotic origin for the disturbance. It will simply mean what it says.

To resume. The first of the psychological commonplaces bearing intimately upon psychotherapy is that if we are expecting a sensation we appreciate it to the full when it arrives; while, conversely, in moments of detachment, many a stimulus beats idly upon us which would be considered quite pronounced if we were attentive to it. For example, how trifling a sound will not the ear detect when attention is concentrated for the purpose, and how loud a one may pass entirely unobserved when attention is absorbed in other directions. Similarly in the heat of a game an injury may pass unnoticed which if inflicted in cold blood would constitute a decidedly disagreeable experience. Here, obviously, is a useful counterpoise for the subjective exaltation of the neurotic, if only it can be brought into practice.

Secondly. Minor disturbances of function occurring without known cause are common in the healthy. They must depend upon some trivial disarrangement, chemical perhaps, or what you will, but whatever their cause it is essentially transient and unimportant. For example, there is the spontaneous twitching of an eyelid which most people have experienced, an occasional cramp, a momentary twinge of pain here or there which passes at once or soon and is never explained. The existence of these disturbances is of no intrinsic consequence, but they are evidence that the working of the normal organism is often not perfectly smooth. And when one reflects upon the vagueness of the sensations we receive by way of the sympathetic system it does not stretch imagination to suppose that if one were to translate the twitching of an eyelid into terms of a disturbance of, say, the alimentary canal, the resulting sensation might well be uncomfortable or in its very vagueness even alarming. Further, stimuli capable of producing a response in a normal subject will certainly act with greater effect in a neurotic one, while the latter will be at the mercy of an additional catalogue of stimuli too slight to produce any response at all in a stable subject. Lastly, the emotional consequences of these anomalies may be expected to assume in the neurotic a prominence proportioned to the latter's exaggerated sensibilities; and this, in fact, is constantly the case. These arguments must in the nature of things be somewhat nebulous, but they offer, I think, a reasonable explanation of the apparently causeless symptoms which are met with daily yet come to nothing; and a working hypothesis which will explain to a neurotic patient the bewildering multiplicity of his sensations is essential to the practice of psychotherapy.

Thirdly. Let me note that any considerable mental agitation, even when the emotion is exhilarating, tends to upset function in a good many people; while when the emotion is depressing it will affect unfavourably all but a small minority of ordinary individuals. The after-dinner speaker, unless case-hardened by experience, seldom does much justice to the food he has come to eat, at all events, until he has punished the wine. The billiard-player who is unaccustomed to play for money or in public commonly finds that these unfamiliar adjuncts to a game disorganise his accustomed power of coördinating hand and eye. As to the depressing emotions, I suppose there are few people so stolid as to be able to deal honestly with a meal offered them during the height of the distress occasioned by some overwhelming personal catastrophe; or, to put a milder case, let me suggest that my readers eat with more appetite amid pleasant and convivial surroundings than they can summon for the solitary discussion of a tough steak, served on a thick cracked plate and a dirty tablecloth, in a dingy eating-house. If the normal and healthy show this amount of dependence upon their emotional states it is easy to see how much the neurotic will suffer if he allows his emotions to run riot. Psychotherapy must teach him this piece of physiology and urge him to put it into practice according to the considerations given in the ensuing paragraph.

Fourthly. It would be an error to suppose that the emotion resulting from a given stimulus in a given individual is a fixed quantity; for emotional states are seldom instantaneously developed, but are the product of mental processes; and these, in their early stages at least, are more or less controllable. For instance, we speak of a man "working himself into" a rage or a fright or what not, and we know that if such emotional outbreaks are to be governed at all they must be attacked at or near their inception. "Obsta principiis" is therefore as truly the motto for the victim of florid emotions as it is for the victim of tuberculosis or cancer.

Fifthly. Since it is certain that attention increases appreciation of stimuli, and that a large proportion of neurotic sensations depend upon trifling derangements, it follows that a conscious and cool disregard, exercised by the patient, would be the ideal method for meeting these multifarious anomalies. This, no doubt, is what Christian Science achieves by employing religious exaltation. But if one seeks to urge this view on reasoned grounds, one is likely to be met by the somewhat nettled rejoinder that the patient has already "fought against" his ailment to the utmost of his power. It is on this account most necessary that both doctor and patient should appreciate that "fighting against" subjective manifestations is a wasteful and irrational method of obtaining what can often be managed more easily by other manœuvres. I can best explain what I mean by an example which a good many of my readers can put to the test in their own persons if they have the necessary enthusiasm. Let any determined and inveterate smoker set about to diminish his consumption of tobacco without positively abjuring it. He will then find that with each recurrence of a legitimate opportunity for smoking—according to the bargain he has made with himself—the temptation to exceed the self-prescribed limit recurs anew, and that it really requires a

painful exercise of constancy to abide by his determination. But let him now abjure the drug altogether, dismissing the possibility of using it completely from his mind, and he will find his undertaking an infinitely lighter matter. For in the entire absence of all reinforcement the mental associations built up by long habit become atrophied with surprising quickness, and this without the sense of constantly recurring effort so prominent in the earlier case. This is, of course, the reason why a reformed drunkard requires much more constancy of will to convert himself into a moderate drinker than would suffice to make him a total abstainer. An analogous reasoning may fairly be applied to the victim of multitudinous, though inherently trifling, symptoms. Fighting against them implies continual effort, continually recurring concentration upon the symptoms, and withal a development of self-pity at the burden of the business, and these together are most unfavourable to success. But if the patient can be roused to a pitch of hardihood which will enable him to take the upper hand and, fortified by the conviction that nothing formidable lurks behind his symptoms, to meet them when they come with a cool, disdainful determination not to bother his head about them, the battle is half won. For the mental placidity thus attained is itself a most potent sedative of the lesser functional derangements, and offers besides a favourable field for the action of such physical remedies as may be thought desirable. This may seem an impracticable ideal, but pains and patience and tact can accomplish much towards it in suitable instances.

Sixthly, and to conclude this part of the subject, it is a blunder to believe, as I long believed, that defective self-control is an element inherent in the neurotic. There is in my opinion no essential connexion whatever between them. For just as some people who pass for normal are self-controlled and some the reverse, so there are some neurotic people who belong to the loudly-lamenting class and some whose morale is of a high order. I mean that they put up uncomplainingly with a degree of mingled bodily and mental distress which, supposing that it could be reproduced in the critics who blame them when they do complain, would make those critics less confident of their superiority. This is a mere assertion and does not admit of proof, since we have no measure for distress. But everybody must know of people who are constantly ailing vaguely and are reputed to be *malades imaginaires*, yet who under circumstances of stress and anxiety exhibit fortitude, self-sacrifice, and endurance which anyone might be proud of; and it is not likely that those who can make little of grave objective troubles will yield without a struggle to trifling subjective ones, as on a superficial view they are often suspected of doing. The truth, I believe, is that people of this kind have often been pretty heavily taxed before they complain at all, and that the reception accorded to their complaints, coupled with the fact that there is so little to show for them, does not make the troubles any easier to put up with. The material point emerging from all this is that in a great many neurotic people who come for treatment of a physical symptom, that symptom is not, as it is made to appear, the first and paramount evidence of ill-health, but is, in fact, a late and chance product of those interactions between functional disturbance and emotional reply to which attention has been drawn already. But the patient will of his own motion say nothing of his antecedent discomforts and apprehensions. It is likely enough that he has hailed his definite physical symptom with delight as offering at last some tangible explanation of the preliminary phase. But unless the doctor can detect and penetrate the disguise in which the timidity or secretiveness of the patient has enveloped the truth, though he may effect a temporary cure by vanquishing constipation or anchoring a kidney, or stitching up a prolapsed uterus, his triumph is in danger of being shortlived.

III.—*Outlines of Practice.*

In the hope that I have taken my readers with me as regards the foregoing facts and presumptions, I will now try to indicate the types of malady favourable to the application of the precepts inculcated. The position can be stated quite simply in general terms. There is only one measure of the suitability of an illness for treatment with the aid of psychotherapy, and that is the measure of its emotional and ideogenic ingredients, provided always that rational faculty is not seriously in abeyance. There is practically no place for it in urgent and acute physical illnesses, nor in the graver developments of chronic ones; for in proportion as physical disturbances are profound, emotional ones tend to sink into insignificance. Nor can it be employed, I imagine, for developed psychoses, since an appeal to the reason is the essence of the practice. But of such psychoses I have no experience. On the other hand, it is applicable, in a greater or less degree, to a large assortment of chronic maladies of little urgency, however recalcitrant they be to treatment; to neurasthenic states, especially chronic ones; to the milder types of hysteria, and to a great variety of physical symptoms masquerading as physical diseases in the fashion I have described. These masking symptoms may be situated anywhere, and their position gives no guide to their character, but on the whole they appear most often in the guise of stomach symptoms.

The field of operations being so wide as it is, the practitioner must be armed with some means of knowing when he is face to face with a case suitable for psychotherapy. Often enough the emotional element can be detected at once, while at times it is rigorously concealed. There are, however, certain indications which are of assistance in determining it. Those which I have found most useful are the following.

(a) The character of the symptoms.—As is well known, the most constant characteristics of neurotic symptoms are vagueness and multiplicity, alone or together. An account of such symptoms, even when given with the most matter-of-fact air possible, should raise the suspicion that they are in part at least neurotic.

(b) The patient's manner of recounting his symptoms.—A self-contained neurotic patient will often succeed in veiling his character so long as he is on formal terms with his doctor. But with growing intimacy self-control tends to suffer occasional lapses which permit a peep at the real individual. Thus, a man may carry off his first interview with an absolutely impenetrable air of unconcern, yet at a later one may show by some trifling manifestation that he is labouring under an emotion not justified to all appearance by the state of his physical health. For example, his eyes may become momentarily suffused with tears, or he may be betrayed into an occasional superlative foreign to his previously indifferent utterances. Such things throw the strongest doubts upon the genuineness of the careless air, and suggest that whatever else the patient may need, he needs consolation and reassurance.

(c) The state of the knee jerk.—Whenever it is difficult on other grounds to form a judgment of the emotional state of a patient, the knee-jerk is a valuable aid, for this investigation takes him off his guard. Any considerable exaggeration of the knee-jerk, in the absence of other evidence of organic nervous disease, betokens a patient whose nervous irritability is exalted.

It follows, then, that the first step in practice is to attain a sufficient degree of intimacy with the patient to allow of a fairly accurate estimate of his temperamental condition at the time, and of the view he takes of himself. If it appears quite certain at the first interview that the emotional component of the illness is negligible, physical treatment will do all that can be done. If there is a doubt it is best to temporise and wait for further evidence. If, on the other hand, there is good evidence of a large emotional element in the case, the next step is to identify and appraise the physical basis, if it can be found. For just as it is futile to treat with aperients alone a man whose illness really depends upon an undetected fear of cancer in the rectum, though his complaint is of constipation, so it is futile to treat by reassurances alone a man whose multitudinous symptoms are founded upon, and continually reinforced by, an undetected nasal polypus or stone in the kidney. Confident though I am that emotional components bulk very large in the sum total of many diseases which present themselves to view as mainly physical, I am equally confident that in a large proportion of such cases there is an organic basis not to be neglected with impunity. Undoubtedly some functional derangements are purely ideogenic—e.g., hysterical paralyses of the mimetic order; but by comparison with the vast total of symptoms of whose physical cause we are ignorant, these instances are relatively rare. It is true that if there be physical sources for this great collection of symptoms they must be essentially unimportant, since commonly the symptoms are transient and do not develop a physical lesion

which can be identified. Still this does not prove that a lesion has not existed; and experience of such diseases as disseminated sclerosis warns us that symptoms regarded at their inception as physically baseless (or "functional" in the loose but special meaning of the word) may be shown by subsequent events to have had a sufficiently material foundation. I do not wish to suggest by this example that an ominous significance should be attached to these unassorted symptoms, but merely to urge that the physical aspects of a disease should not be neglected though its emotional component be never so greatly over-developed. To disregard this caution and rely upon psychotherapy alone, unless in most exceptional instances, is to court disappointment and to throw undeserved discredit upon a useful ally. Consider neurasthenia for example. No one, I take it, would deny that there is a pronounced ideogenic factor in most cases within this category; yet it is waste of time to treat neurasthenia by psychotherapy alone, especially when the fatigue-element is prominent. For it is pretty certain, though unproven, that a metabolic fault is at the bottom of neurasthenia, and it stands to reason that this fault cannot be met by arguments. This warning is of particular moment, for there is the same tendency for one interested in the psychical side of physical diseases to overlook organic faults as there is for the pure materialist to overlook emotional ones. Therefore it is an urgent matter that physical examination should be thorough.

Yet even here there is room for the play of judgment, for whereas there are some of these patients who will not be persuaded of their freedom from organic lesions unless after the most protracted and impressive investigations, there are others in whom the intricate procedures required for accurate diagnosis may themselves do harm by adding fuel to self-suggestions. In dealing with patients of the latter stamp it may be better practice to hazard an optimistic view somewhat insecurely based (unless it involves the risk of overlooking some grave but remediable lesion like early carcinoma), rather than to admit, even temporarily, the possibility of serious mischief. There can be no formal rule in such matters, and the physician must be guided by common-sense and intuition in selecting the course most likely to be beneficial to the patient in hand.

Let us suppose, then, that doctor and patient are by now on secure and fairly intimate terms, such terms I mean as have made the patient appreciate that the doctor understands him and is genuinely interested to help him. A frank relation of this sort is quite indispensable, for the sensitive type of patient most likely so be benefited by psychotherapy is precisely the type of patient most ready to take umbrage at any seeming suggestion that his sufferings are not real; and it is not an easy matter to persuade a man that one accepts the reality of a symptom, while at the same time one is proclaiming it in part at least ideogenic. Let us suppose, further, that the physician has satisfied himself of the existence of a large emotional element in the illness, and has set about trying to remedy the physical fault by the ordinary means. The next step is to select the moment suitable for embarking upon the rational explanations by which it is hoped to point out to the patient the path along which he has developed the mind-made factor of his malady, in order that he may be permanently protected, to some extent at all events, from similar tricks of fancy. Much depends upon a wise choice in this respect. For to ask attention for rather complex arguments from neurotic patients reduced by long ill-health to the last pitch of physical and emotional frailty is palpably ridiculous. The first care must be directed towards improving the physical health, if this is at all seriously impaired, by rest, feeding, massage, electricity, exercise, and so throughout the well-known category of good servants in such cases. Yet even during this period it is possible to do a good deal by speech and manner to reassure and encourage the patient, and gradually to restore such a degree of placidity and hopefulness as will afford a footing for the philosophical considerations presently to be employed.

And when the fit moment arrives, early in some cases, late in others, according to the bodily condition, how is the philosophic teaching to be applied? The answer is easily put on paper. It is to be applied by means of conversations based upon the postulates enunciated above, or such of them as seem to fit most accurately the case in point, or any others which the wit of the practitioner can conjure to his aid. The patient must be brought to know these elementary fragments of physiology and psychology, and urged to apply them to his own salvation. He must be tempted to abjure self-pity and ensue stoicism in some cases; in others, to realise the incubus of too ready and unjustified apprehensions; in others again to know that vague sensations are but poor guides for accurate inference. And always the aim must be to cultivate optimism and placidity, and the faculty for criticising and viewing with scepticism the rash conclusions concerning the relations of symptoms and diseases to which such patients are commonly given. I refrain from attempting any detailed description of the steps to be followed in these arguments: partly because there is no royal road for every case, partly because the trifling consolations, platitudes, and confidential exhortations, which will help a sick man who knows one is trying to help him, would be laughable if set down formally. Such readers as I may have kept to this point will know without telling of mine how best to suit their arguments to the changing circumstances. Patients vary greatly in the ease with which they are approached, and some are almost unapproachable. But patience and open friendliness will succeed if success is possible. I ought before concluding to say that the method I have tried to describe is hard to use in the out-patient room, partly on account of the time it takes, partly because publicity drives into their shells the patients most likely to be benefited. So I do not advise anyone to begin his experiments in this direction in the presence of other patients or before a roomful of students. With this I leave the subject, hoping that I have made out a case for treating by psychical means the mind-made factor in physical or pseudo-physical illnesses, the neglect of which factor has long been something of an opprobrium to medicine.

Devonshire-place, W.

Medical Societies.

MEDICAL SOCIETY OF LONDON.

The X Ray Diagnosis of Pulmonary Disease.

A MEETING of this society was held on Jan. 8th, Dr. J. MITCHELL BRUCE, the President, being in the chair.

Dr. G. HARRISON ORTON read a paper on the X Ray Diagnosis of Pulmonary Tuberculosis, in the course of which he said that his object was to try to show how pulmonary tuberculosis even in its very early stages could be demonstrated by the X ray examination, but before going further he insisted on the importance of regarding the examination as an additional aid to diagnosis, a method to be used not in place of, but in conjunction with, every other method at their disposal. As no one other method taken alone was infallible, neither was the Roentgen method, but there were many instances where its employment would enable a definite opinion to be formed in cases which would otherwise have remained doubtful. In utilising the Roentgen method they were bringing into play another, and in most of them the most highly developed, sense—namely, the sense of sight—and it could not but be to their advantage to be able to control with the eye the findings of the hand and the ear. It seemed to be the idea of many that the X ray examination consisted merely of putting a plate upon the chest and making an exposure, but he need scarcely say that that was not the case. A careful screen examination with every detail of technique properly carried out by a skilled observer was of the utmost importance, and that must be followed by the skilled interpretation of a satisfactory negative or negatives. Hasty and perfunctory examinations and imperfect technique had been, and were still, responsible for many errors which tended to bring that method into disrepute. He had not time to describe the appearances seen in all the positions employed, but would consider those seen in the postero-anterior and antero-posterior examinations—i.e., when the screen was placed either on the anterior or posterior surface of the chest. The X ray tube, of course, was on the opposite side of the chest to the screen in both cases. The appearances seen in those two positions were so similar that the same description would apply to both if he pointed out afterwards the slight differences which enabled them to distinguish between the two. What they might call the radioscopic image of the normal chest presented three vertically disposed zones, a median which

was dark and corresponded to the shadows cast by the vertebral column mediastinal contents (including the heart), and the sternum, and two clear lateral zones which were situated on either side of the median and corresponded to the areas occupied by the lungs. They were crossed by the curved shadows of the ribs, and in the upper part by the somewhat denser shadows of the clavicles; they were bounded above by the shadows of the first ribs, laterally by the shadows of the overlapping ribs and lateral walls of the thorax, and below by two dark dome-shaped shadows, which rose and fell with the movements of respiration and corresponded to the diaphragm. When the screen or plate was placed on the anterior surface of the chest the lattice-work effect caused by the crossing of the ribs was a very marked feature, which was almost absent when the screen was on the posterior surface, and that was due to the fact that the anterior portions of the ribs were much less dense than the posterior, dense enough to cast a very distinct shadow when the plate was almost in contact with them, but being very much less distinct when it was at such a distance from them as it must needs be when placed on the posterior surface. The heart being nearer the front than the back of the chest the shadow of that organ was sharper and more distinct when the screen was on the anterior surface. In addition to what they might call those grosser shadows there were to be seen on either side of the median shadow certain somewhat ill-defined shadowy lines, which became less and less evident as they passed from the region of the root of the lung towards the periphery and were more marked on the right side than on the left. He would not weary them with all the explanations which had been put forward to account for those; they were due to the vessels and bronchi radiating from the roots of the lungs, in the main he thought due to vessels which were more likely to cast shadows, being filled with blood, than the bronchi which were filled with air. In addition to those radiating lines there were to be seen also near the root of the lung on either side certain opaque spots and circles, no doubt due to vessels and bronchi seen in cross section. It was important that those should be recognised as normal shadows. Having briefly touched upon the normal appearances, Dr. Orton proceeded to investigate the various departures from the normal which could be made out in pulmonary tuberculosis. Omitting very advanced cases the following were the chief changes, and one or more of them would be found to be more or less marked in all cases: (1) A dimness and failure of one or both apices to brighten on deep inspiration; (2) the movement of the diaphragm was restricted on the affected side or sides, that restriction being as a rule in the lower part of the excursion; (3) the heart in a large majority of early cases was smaller and more vertically placed in the chest than normal; and (4) definite shadows were cast by the diseased portions of the lung.

EDINBURGH MEDICO-CHIRURGICAL SOCIETY.

Exhibition of Cases.

A CLINICAL meeting of this society was held on Dec. 21st, 1911, Mr. J. M. COTTERILL, the President, being in the chair.

Dr. DAWSON TURNER showed a case of Leucoplakia in a man aged 50, and one of a male child, aged 1¾ years, with a Congenital Nævus at the lower part of the left cheek, in both of which the condition disappeared under exposure to radium for 60 mgm. hours and 37½ mgm. hours respectively.

Dr. JOHN EASON showed a case of True Gout in a man, aged 70, who had been a heavy beer-drinker. His father was by occupation a butler. There were numerous gouty deposits of varying size; one over the right olecranon was of the size of a golf ball. The disease began 14 years ago with an attack in the great toe. The deposits were either "shotty" or soft and almost fluctuating, and they were chiefly composed of sodium biurate and organic matter.

Mr. D. P. D. WILKIE showed two cases to illustrate the beneficial effects of salvarsan. 1. A woman nine months after this treatment had been adopted for pronounced tertiary specific lesions. She had contracted syphilis 25 years ago and had been treated in the lock wards of the infirmary for several months for severe secondary lesions, and mercurial treatment had been continued until the present year. For 15 years she had regularly attended as an out-patient for syphilitic psoriasis and leucoplakia. Salvarsan, 0·5 grm., was given intravenously in March, 1911. The psoriasis disappeared in 15 days, but at first the leucoplakia and fissured tongue did not seem to improve. Of late, however, great improvement had resulted. 2. A woman who had suffered from a specific ulcer of the right leg for six years in spite of local and general treatment, and had given birth to still-born children. Salvarsan was administered intravenously, 0·5 grm., in March, 1911. The ulcer healed within four weeks, and in October she gave birth to a healthy child. There had been no recurrence of syphilitic lesions in either case up to the present or after an interval of ten months.

Dr. D. CHALMERS WATSON showed a case of early Rheumatoid Arthritis, in which recovery took place under careful regulation of the diet with daily administration of saline aperients. He thought rheumatoid arthritis should always be cured if taken early in the disease. The source of disease lay in the alimentary, urinary, or genito-urinary tract.

Professor FRANCIS M. CAIRD showed: 1. A male, aged 27, who had suffered from Tropical Abscess of the Liver and Empyema which was incised after resection of the eighth rib and drained, the pus containing the colon bacillus or perhaps that of Mediterranean fever. After draining amœbæ were discovered in great numbers. (He had had dysentery in Burma.) Each night he received 20 grains of chloral hydrate and a little later 15 (subsequently increased to 20) grains of ipecacuanha in pill form. The discharge ceased as if by magic, and though the sinus was still open there was hardly any discharge. 2. A female, aged 32, who all her life had suffered from extroversion of the bladder, in which an epithelioma developed. The neoplasm and mucous membrane of the bladder were removed, entailing division and removal of part of the right ureter, and the stump had to be implanted in the cicatrix. The operation was performed in May and there had been no return of the trouble; but in the right renal region an ascending pyelitis had developed owing to the removal of the valvular action of the lower end of the ureter which had previously prevented the ascent of any infection.

Dr. EDWIN BRAMWELL showed a case of Hysterical Contracture of the Hip in a single woman aged 21. The condition dated from a fall down a flight of stairs two years previously. She had twice been in hospital for the condition and had been ordered to wear a thick-soled boot for "hip-joint" disease. On admission to the Edinburgh Royal Infirmary on Nov. 11th, 1911, there was extreme lateral curvature with tilting of the pelvis upwards and to the left. There was great apparent shortening of the left leg. Examination with the X rays showed no disease of either hip-joint. On Dec. 7th the patient was examined under chloroform, when the deformity completely disappeared under the anæsthetic. The subsequent treatment consisted in isolation and suggestion and rapid recovery had since then taken place. The wearing of the high boot had probably kept up her idea of real disease.

Mr. C. W. CATHCART showed several cases of Fracture to illustrate the good effects of massage and movement in producing satisfactory functional results, although the restoration of the contour of the bones was not perfect.

Mr. GEORGE L. CHIENE showed a girl, aged 7, after wiring for Oblique Fracture of the Shaft of the Left Femur.

Mr. HENRY WADE showed:—1. A case of Right Nephrectomy by the transperitoneal route for acute consecutive suppurative nephritis. The patient, a married woman aged 40, had been sent to the infirmary as a case of acute suppurative appendicitis; but as the frequency of micturition with dysuria had dated from before the onset of the acute symptoms acute suppurative nephritis was diagnosed. 2. Cellulitis of the leg due to an Anthracoid Organism. A man, aged 19, was admitted on Nov. 11th, 1911, with acute cellulitis of the leg (thought to be osteomyelitis). The inflamed area was incised and the tissues were found to be almost necrotic, with no free fluid pus; improvement was very slight. An inflammatory focus which formed on the thigh was incised four days later with similar appearances and similar result. On pathological examination of the fluid obtained at this second operation an organism

identical with the true anthrax organism was found, but clinically the symptoms were not like those of anthrax, and the virulence of the organism was small as compared with the true anthrax organism; it was not toxic to mice. Under Sclavo's serum rapid improvement followed.—The PRESIDENT stated that he had met with an exactly similar case which rapidly recovered after incision merely.

Mr. ALEXANDER MILES showed:—1. A patient whose Fingers had been Amputated on account of being crushed between toothed wheels. The granulating surface had been covered over by making a pocket in the skin of the anterior abdominal wall and fixing the hand there until adhesion had taken place. The lower margin of the skin pocket was divided and a plastic operation had thus been completed. 2. A female patient to illustrate a stage in the restoration of the nose and upper lip due to Syphilitic Ulceration. To support a flap which Mr. Miles intended to take from the forehead, a bony septum had been formed by implanting a slice of bone obtained from the astragalus of another patient on whom arthrodesis of the ankle had been performed.

Mr. J. V. PATERSON showed a case of Arterio-venous Aneurysm of the Orbit in a woman who three weeks previously had fallen down a stair. The lesion was due to a communication between the carotid artery and the cavernous sinus.

ROYAL ACADEMY OF MEDICINE IN IRELAND.

SECTION OF MEDICINE.

Rat-bite Fever.—Splenomegaly.—Pancreatic Cyst.

A MEETING of this section was held on Dec. 15th, 1911, Sir JOHN W. MOORE, the President, being in the chair.

Dr. J. F. O'CARROLL gave an account of a case of Rat-bite Fever. The patient had been bitten by a rat in the lip in March, 1910. After some time the submaxillary glands enlarged, and there were recurrent attacks of remittent pyrexia. Each attack lasted four or five days, with an interval between each of three or four days. A month afterwards the patient developed a very marked nephritis, with an accompanying pleural effusion. By the end of 1910 the patient had so far recovered as to be able to return to heavy work, and has since remained well.

Dr. W. A. WINTER gave an account of a case of Splenomegaly in a man aged 35. His personal and family history were good. Enlargement of the spleen was noticed first in 1905. The patient had had hæmatemesis on several occasions. The blood showed a moderate degree of anæmia, with distinct leucopenia, absence of abnormal forms of leucocytes and of nucleated red corpuscles. The spleen had altered very little in size since 1907. The liver was not enlarged; no jaundice, no ascites. Dr. Winter suggested that the case might eventually show the full picture of Banti's disease. He had advised splenectomy, which was refused by the patient.—The PRESIDENT asked if the liver was cirrhotic. As to the splenic murmur he remembered attention having been called to this before in a case of enlarged spleen.—Dr. T. P. C. KIRKPATRICK said that he had under treatment a boy, aged 8, suffering from Banti's disease. There was a history of his stomach having been trampled upon five weeks previously, and a good deal of blood had been vomited a fortnight afterwards. A very much enlarged spleen and liver were discovered. There was no jaundice. Von Pirquet's reaction was negative on two occasions. Operation was advised to get rid of ascites. Examination of the blood showed a certain amount of anæmia, but no marked departure from the normal in the number or variety of white cells. The child went on well for some time, but then had another severe hæmorrhage, followed by swelling of the abdomen, and he was again admitted to hospital. The blood then showed a reduction of the red cells, with the hæmoglobin considerably reduced. The enlarged spleen was removed, but the child had not done well since, and recovery appeared doubtful. It was his opinion that if good results are to be obtained operation must be done as early as possible.—Dr. W. M. CROFTON said that he had examined the blood in both cases. In Dr. Winter's patient there were a large number of mononuclear cells in the first count, the classification of which would be difficult. The patient at one time suffered from micro-sepsis, and he thought that this might have some bearing on the condition.—Dr. WINTER, in reply, said that the great risk of operation seemed to be the difficulty of controlling the hæmorrhage, which arose through having to turn over the spleen so as to get at the vessels. However, taking everything into consideration, he was very much disposed to recommend operation, and he thought that all the literature on the subject was in conformity with this.

Dr. T. G. MOORHEAD reported a case of Pancreatic Cyst, which was discussed by the PRESIDENT, Dr. CROFTON, Dr. J. A. MATSON, and Mr. F. K. CAHILL.

HARVEIAN SOCIETY.—The annual general meeting of this society was held on Jan. 4th, Mr. J. Ernest Lane, the President, being in the chair. The election of officers for the ensuing year having been proceeded with, the President delivered his address, entitled "Unity in the Medical Profession." Having thanked the members for their kindness to him during his term of office, he briefly referred to the work of the past year, and then began his address by reading an extract from a medical gazette of June 20th, 1835, at which time the St. Albans Memorial was presented to the Poor-law Commissioners with reference to the appointment of medical officers for attendance upon the poor. He then went on to discuss the present Insurance Act, more particularly with reference to the number of patients that every medical man working under the scheme would have to attend and the remuneration for the same. He briefly alluded to the future financial position of voluntary hospitals, and ended by urging upon his listeners the importance of unity of purpose. Mr. Lane then vacated the chair, and Dr. H J. Macevoy, the new President, was inducted. Subsequently a smoking concert was held. About 50 members and visitors were present.

SHEFFIELD MEDICO-CHIRURGICAL SOCIETY.—A meeting of this society was held on Dec. 21st, 1911, Dr. H. E. Knight, the President, being in the chair.—Dr. Percival J. Hay, in a paper on the Pathology, Diagnosis, and Treatment of Corneal Ulcer, discussed the clinical and pathological characters of serpiginous ulcer and the etiology of the disease. He showed that the age-incidence of the hypopyon ulcer coincided with that of pneumonia in adults, a circumstance which seemed to have escaped notice, and which suggested that after middle life there was a lowering of resistance to the pneumococcus. The statement of certain German authors that the disease was a seasonal one and was favoured by exposure to heat was shown to be based on false premisses and to be only partly true. The seasonal variation found in country towns was absent in manufacturing and mining centres, such as Sheffield and Birmingham, and was due to increased dust and dirt in agricultural occupations during the summer months. Statistics covering more than 1700 cases demonstrated that the visual results were very unsatisfactory. Over 50 per cent. of the cases ended in vision less than 6/60. No treatment could be considered satisfactory that did not secure the average vision of 6/18. In the best series of statistics only 25 per cent. of the patients obtained 6/18. Other statistics showed percentages as low as 10 and 7. By instituting new methods of treatment, in which greater attention was paid to the treatment of the conjunctiva and treatment in the open air, he had obtained vision 6/18 in 40 per cent. of his hypopyon cases. Details of his method of treatment were given, and the paper closed with a discussion of measures of prevention.—Dr. F. H. Waddy, in a paper on Four Cases of German Measles, referred to the confusion in nomenclature of the diseases variously known as rubella, rubeola, and roseola, and quoted Nothnagel's opinion that the disease known as German measles was not entitled to a separate existence, and the later opinion of Griffith that its existence was denied only by those who had not seen it. Dr. Waddy urged that this disease presented sufficient distinctive characteristics, especially peculiarities of the rash, to admit of early diagnosis with as much certainty as in the differentiation of chicken-pox from small-pox. He related his four cases of German measles occurring in one family and presenting a strong resemblance to scarlet fever, differing from it, however, in the period of incubation, the symptoms of invasion, the

nature of the eruption, and the condition of the throat and tongue. None of the patients had ulceration of the throat, but the glands of the neck were swollen. The interval in the eruption between the first case and those succeeding it was 24 days, and between these and the last case 22 days. The first case was followed by rheumatism and endocarditis. The second case occurred immediately after measles and was followed by suppuration in the ear, and three weeks later by acute nephritis. The cases of the parents presented no important complications or sequelæ. Profuse desquamation occurred in all the cases except the second, in which there was no trace of it.—Mr. F. A. Hadley showed the following specimens of uncertain pathology: (1) Cysts filling and distending the whole abdomen in a child nearly 2 years old, and originating in tissue about the pancreas; (2) an Appendix converted into a large cyst, containing jelly-like mucus; and (3) an Appendix from an old woman, aged 63, gangrenous in its whole length.—Dr. Ralph P. Williams showed a girl suffering from Melanotic Sarcoma. The child's general health was quite good. It was proposed to remove the growths and to treat with Coley's fluid.

NOTTINGHAM MEDICO-CHIRURGICAL SOCIETY.—A meeting of this society was held on Dec. 20th, 1911, Dr. F. H. Jacob, the President, being in the chair.—Dr. S. E. Gill, in an address on "Ringworm," remarked that ringworm was a contagious skin disease characterised by (*a*) the formation of a mycelial network on the surface of the skin, and (*b*) an infection of the hairs and hair follicles, these characters being usually present together in varying proportions, but often with great predominance of one or the other. The organisms causing it were two—the trichophyton and the microsporon. The latter was much the more resistant to treatment and constituted about 60 to 90 per cent. of all cases found. Ringworm was a disease of children, especially between the ages of five and nine, hence its importance from a school medical officer's point of view. As it was necessary that all cases should be excluded from school on account of its contagiousness, and as from 1 to 4 per cent. of school children, according to locality, were affected, this disease caused a very large loss of grant to local education authorities, especially as the time which elapsed before cure took place was many months, and occasionally years, by the ordinary methods employed. The usual treatment was by (1) antiseptics, which inhibited the spread of the disease, but had little effect in curing the parts affected; (2) counter-irritants, which did good in so far as they caused epilation; and (3) epilation pure and simple, such as X rays, which in the most capable hands cured in about seven weeks as compared with many months by the other methods. The dangers of X ray treatment were much exaggerated, permanent baldness being very rare, and colour changes also were rare. From an administrative point of view it was advisable that the exclusion of ringworm-children from school should be in the hands of one person, and consequently their readmission should also be in his hands. If general practitioners would send their cases to the medical inspection department from time to time for microscopic examination and report it would be useful to them in dealing with a troublesome disease from which very little credit was to be obtained with their patients, and would also be of service in helping the school authorities to prevent the return of children to school who were still in an infective condition.—In the discussion the President spoke of the disappointing results from the use of copper ions, which he had tried extensively.—Mr. R. Wood (Ilkeston) favoured the use of sulphurous acid (B.P.).—Mr. H. G. Ashwell and others spoke of the very disappointing effects of ordinary treatment, even when carried out systematically in institutions.

LIVERPOOL MEDICAL INSTITUTION.—A meeting of this society was held on Dec. 21st, 1911, Dr. T. R. Bradshaw, the President, being in the chair.—Mr. A. A. Bradburne reported the case of a family in which Ptosis and Immobility of the Eyes had been present in five generations, being traceable as far back as 1710. He described the condition of the six members who are at present alive and of seven who are known to have the affection.—Dr. W. B. Warrington referred to a case of congenital but not hereditary ophthalmoplegia that he had recorded.—Dr. E. W. Hope read a note on the Compulsory Notification of Pulmonary Tuberculosis, in which he traced the various stages through which the notification of this disease had passed, and called attention to the fact that after Jan. 1st all cases of pulmonary tuberculosis were to be notified as if tuberculosis were included in the Infectious Diseases Notification Act, 1889.—Dr. W. Murray Cairns read an account of difficult delivery, in which he had performed the operation of kleidotomy.—Mr. R. E. Kelly showed a boy, aged 9, who had been run over by a motor-car and on whom he had performed splenectomy. He was admitted to the Royal Infirmary suffering evidently from internal hæmorrhage, but no exact diagnosis could be made. He was operated on within an hour of the accident. The spleen was severely lacerated and had to be removed. Recovery was uneventful. The boy now (six months later) appears perfectly healthy, with the exception of some slightly enlarged lymphatic glands.—Dr. Campbell showed that the blood had undergone the following changes: Red cells, increased hæmoglobin index but no poikilocytes or erythroblasts; white cells, increased lymphocytes, a basophilia of 2½ per cent., and an eosinophilia.—Dr. H. R. Hurter related that in a case of his in which the spleen had been expelled, owing to torsion of the pedicle, there were no blood changes.

Reviews and Notices of Books.

Manual of Surgery. By ALEXIS THOMSON, F.R.C.S. Edin., Professor of Surgery, University of Edinburgh; Surgeon to the Edinburgh Royal Infirmary; and ALEXANDER MILES, F.R.C.S. Edin., Surgeon to the Edinburgh Royal Infirmary. Vol. I., General Surgery. Fourth edition, revised and enlarged, with 297 illustrations. London, Edinburgh, and Glasgow: Henry Frowde and Hodder and Stoughton. 1911. Pp. 809. Price 10*s.* 6*d.*

IN this, the fourth, edition of this well-known text-book, the first volume of which has just been published, the authors are making some important changes in the general arrangement of the work; they are adding a third volume, which will deal with operative surgery. In this first volume general surgery is considered, while the second volume will be devoted to regional surgery.

One of the most important points that strike a reader, even in opening a work on surgery, is the manner in which it is illustrated, for illustrations are the best means of giving to the reader rapidly an impression and an interpretation of the text. They are, so to speak, the illuminant which sheds light on the author's train of thought, and in this volume the illustrations are numerous and well chosen, and they fulfil their object. The process by which they are reproduced is good and gives a soft effect. The many skiagrams should prove useful to the student, and they show good detail.

It is difficult to mention any part as pre-eminently good, when all is good, but we are inclined to think that the account of fractures is especially deserving of approval, for this subject, often difficult for students, is described as clearly as possible. Of all fractures those of the neck of the femur appear to cause students the greatest difficulty, but the description given here is clear and should be comprehensible to every one. We are glad to see that an account is given of Chiene's test which is often of value in recognising elevation of either trochanter and yet it is rarely mentioned in text-books. It is used thus: Two lines are drawn, one at the level of the anterior superior iliac spines, and the other at the level of the tips of the great trochanters. Any want of parallelism of these lines indicates an altered position of one trochanter. The modern treatment of fractures is well described.

In the chapter on Tuberculosis, for diagnosis von Pirquet's test is rightly given pre-eminence for practical use. The authors consider that the subcutaneous injection of Koch's tuberculin is not well suited for use on human beings, and Calmette's

conjunctival test is not mentioned, probably as being too dangerous both to the patient's eye and to the surgeon's reputation. Moro's tuberculin ointment test might perhaps have found a place; it has the advantage that no preliminary abrasion of the skin is necessary.

This manual can be recommended to the student and also to the practitioner, for it is clear, concise, and thoroughly trustworthy: it is, and well deserves to be, one of the standard text-books of the present day. We suppose that it is inevitable that the work should increase in size, but we hope that the authors will do their best to keep it within a moderate compass.

Unity in Nature: An Analogy between Music and Life. By C. E. STROMEYER. London: Sherratt and Hughes. 1911. Pp. 589. Price 12*s.* 6*d.* net.

No intelligent reader can fail to find this book of absorbing interest. Mr. C. E. Stromeyer is the engineer-in-chief to the Manchester Steam Users' Association and the author of a well-known book, "Marine Boiler Management and Construction." With reason we are all more or less shy of the metaphysician of to-day, and we welcome with delight the work of a practical engineer on the greatest of all subjects; for, to quote the author, engineers base no conclusions "on false evidence or on sophistical arguments. They abhor every suggestion of finality, for that is a stumbling block to improvement and progress. They lean on analogy, feeling that, from first to last, each experiment is but the analogue of the next one ..... and that there is no end to possible researches and improvements."

Every modern science now rests upon two established principles—the indestructibility of matter and the conservation of energy—and to Mr. Stromeyer there is a parallelism of these two realities—matter and energy—in our world of space and time with the rhythm and melody in the music-world of time. Music, of course, has no existence in space but only in time, while its two constituents differ in a remarkable way. "Rhythm can lead an independent life, as in the drum beating of the Orientals; melody without rhythm is inconceivable; in fact, melody has to be carried, she cannot walk alone, and yet she gives the impression of being the superior."....."Melody loves change, yet she is never without her supporting partner, rhythm; she may leave one musical measure for another and yet she will be recognisable as the same musical theme; but if she attempts to live alone she is dead as a melody." In a similar way we only know of energy when it is in association with its more stolid partner, matter, in our complex world of space and time.

A quite rudimentary idea of the subject of this book may be given by these extracts, but the analogy is so novel that there is a great difficulty in explaining the point of view in the space of a review. After dealing with Matter, Energy, Geology, Evolution, the Creator and His work, Mr. Stromeyer considers What is Perfect Music? and, in the following chapter, Perfect Life and Human Happiness; he then treats of Ethics, Education, Political Economy, State Harmony, and the Reserve Power of the State. Finally, he scathingly criticises some of the prevalent State incongruities and discords. A few quotations will probably give an indication of some of his views and of the simple and clear way in which he expresses them. Thus, speaking of education, he says, "Examinations if necessary at all should be, as regards mental capacities, what mechanical tests should be as regards properties of minerals. ..... The tendency amongst examiners will always be to arrange their tests so as to be able to judge decisively, not what the boy will be, but what he is; ..... so a premium is placed on memory, which more often than not is a sign of weak reasoning power." After comparing the automatic tool machine, which excels in turning out uniform work, with an amateur's lathe, which can do almost anything with any material, he says it is the amateur's brain, not the automatic brain, that can think quickly and correctly on all things, and can deal with any modern event in a rational spirit. About Board School teachers he gives this pregnant sentence: "It is truly surprising that the sturdy British artisans, whose Unions exclude labourers from their trades, should allow the labourers' children to become their children's teachers." In another place he commends the ancient Chinese system of ennoblement, according to which each child would have to pass through a grade that is one degree lower than that of his parent, if noble; consequently, as in China, a man can only rise two grades during life; it would be only possible for him under the most favourable conditions eventually to attain a dignity one grade higher than that of his parent.

When dealing with ethical questions the author suggests that a perfect life requires the maintenance of a due balance between the two opposing functions—reason and instinct. If reason unduly intensifies instinct, immorality results, whereas crime occurs when reason crushes instinct. The analogy in the music world is not adduced, but as instinct is more primitive than reason the reader is led to institute comparison with the imperfect music that results from the predominance of rhythm in drum tattoos (immorality) and the absence of rhythm that kills all musical life (crime).

One or two errors must be noted. Few biologists, we imagine, will agree with Mr. Stromeyer's remarks about the conclusions that have been drawn from Mendel's observations. Napoleon was not the undisputed possessor of a "perfect bodily constitution," while the statement that "repeated doses of opium are demanded" when Bright's disease is threatened is startling. On p. 327 there is a reference to the Greek Testament (1 Cor. vii. 21) which we have been unable to verify, but this may be due to a printer's error.

The scope of Mr. Stromeyer's knowledge, ranging over all the sciences with frequent illuminating historical references, is immense, and we cordially recommend this stimulating book to our readers.

Triumphs and Wonders of Modern Chemistry. By GEOFFREY MARTIN, B.Sc. Lond., M.Sc. Bristol, Ph.D. Rostock. London: Sampson Low, Marston, and Co., Limited. 1911. Pp. 358. Price 7*s.* 6*d.* net.

THE author may well be excused his unbounded enthusiasm over the triumphs of modern chemistry, for they are marvellous. It has been Dr. Martin's lot as a lecturer on chemistry to come into frequent contact with many pupils of different ages and of both sexes who have felt much interest in the new chemistry, as solving the grand questions of the universe in which they live and of the matter which surrounds them on every side; but often these pupils have had neither the leisure nor the inclination to master the technicalities and enter into the minutiæ of the regular text-books of chemistry. He has therefore provided for a wide class of readers who are intelligent without being learned.

The most satisfactory feature of the book is the author's clear exposition of the significance of those elementary chemical facts the importance of which, in the ordinary text-book on chemistry, are commonly left to the reader to find out for himself. The chapters with the headings, "Life on a Nitrogen World," "How Lightning Combines Nitrogen," "Nitrogen in Living Matter," "Problem of Fixing Nitrogen," "Manures," "Will our Food be Made in Future in Chemical Laboratories?" "Circulation of Nitrogen in Nature," illustrate this attitude exactly;

while in the chapters on the element carbon and carbon dioxide will be found some most interesting considerations upon such points as the cycle of carbon in nature, the rôle of coal, the life-history of the diamond, the steadily increasing amount of carbonic acid in the air, the evolution of that gas from volcanoes, its occurrence in effervescent springs, and so on. The chapter on "Fire, Flame, and Spectral Analysis" contains graphic descriptions characteristic of the book. Take, for example, the following: "It seems incredible that man, an animalcule crawling upon a grain of dust flung at random into a fathomless abyss, should have succeeded in actually analysing mighty suns millions, nay billions, of miles away with as much ease as he analyses a piece of rock, or a lump of salt, found to hand on the surface of the earth." Then follows a description in terms perfectly clear to the lay reader as to the part played by the spectroscope in making such an accomplishment simple.

The illustrations throughout the pages are vivid, although in places they are distinctly grotesque. But this counts for little in view of the freedom from exaggeration which marks the text; the temptation which the treatment of fascinating subjects offers to an enthusiastic writer to "let himself go" having been manfully resisted. This book will solve problems which worry many people of an inquiring mind; they will be grateful for the clear glimpse into the nature of things afforded by recent discoveries as expounded by Dr. Martin. The book gives to all not highly equipped in chemistry, physics, and technical knowledge an opportunity of appreciating the greatest phenomena of the universe.

The Real Cause of Stammering, and its Permanent Cure. A Treatise on Psycho analytical Lines. By ALFRED APPELT, Principal of the Institute for Stammerers, Goldington, Bedford. London: Methuen and Co. 1911. Pp. 234. Price 3*s.* 6*d.* net.

No one who has had any long experience with stammerers will be inclined to doubt that their affliction is in the great majority of cases a disturbance on the highest, or psychical, level of nervous function. It would be perhaps too much to maintain that peripheral causation of the condition is impossible, but the facts that plead in favour of the former localisation are impressive in their significance. Stammering, in other words, is essentially a neurosis, and once careful examination has dispelled the likelihood of any extrinsic source for the mischief, the condition should be treated in the light of this knowledge. Mr. Appelt, evidently an enthusiastic follower of the Freudian school, hails in psycho-analysis the panacea of stammering. He has felt it incumbent on him to "remove the veil of mystery" which he supposes has hitherto hung over the treatment of stammering, and has written this book admittedly from the point of view of the stammerer himself. Whether the latter is likely to be impressed or influenced or instructed by the "revelations" of the causation of his trouble furnished by the author is another matter. He will, no doubt, be interested to read that his sexual life begins from the day of his birth; that in his tender years he has come into contact with the sexual problem and "feels a libidinous emotion from his unconscious," which is experienced by him (for some unexplained reason) as dread; that his "mother, father, nurse, or nursemaid is ..... his first erotic love" (one is thankful Mr. Appelt has not employed the even more repulsive language of Freud himself in this connexion); and he will learn that thereafter "introversion of his libido" sets in, that "a superfluity of libido in the child's soul (conscious) and in repression (unconscious) results in the formation of an emotional complex" (whatever that may mean), and that once this is formed the impediment of stammering may develop. Oddly enough, Mr. Appelt seems to be aware of certain difficulties associated with the acceptance of these Freudian commonplaces, for he declares that in these circumstances stammering will set in *in cases where the child is disposed to stammer* (italics ours). Further, after asserting that shock, fright, or disease never produces permanent impediments of speech, he says a few pages later that the emotional complex will not take the form of stammering unless "the speech nerves are weakened owing to heredity, to a shock, or to diseases like whooping-cough or diphtheria."

We cannot follow the author through the long chapters on therapeutics, which may reasonably be expected to be those to which the embarrassed stammerer—his prospective reader—will first of all turn. Yet in them the uninitiated will find, we venture to say, a great deal that is difficult of comprehension, as well as much that is hypothetical to a degree. We can find no hint of possible difficulties in the way of the application of the psycho-analytic method to children, who must form a large, if not the major, portion of the stammerer class. To ask a child to give with concentration and sincerity a detailed account of its life and environment, to enjoin it to allow thoughts to come forward that inner resistances are repressing, to tell it to react in a subjective manner on the stimulus-word, and so on, is absurd. Mr. Appelt embraces whole-heartedly Freud's interpretation of dreams, but it is not clear in what way the pages devoted to a consideration of this very debateable matter can be expected to aid the stammerer, whose knowledge of such scientific jargon as "latent content" and "manifest content" must be limited. It is unfortunate that a slip-shod use of medical terms should occur with some frequency in the book. Stammering is referred to at one time as a manifestation of hysteria, again as a phobia, in another place as a condition akin to writer's cramp. The use of the term "neurosis" by the author is confusing and inaccurate—e.g., "the soil from which neurosis sprang into existence was already prepared by erotic emotion," &c. There is a curious mistake on p. 146 in reference to a statement attributed to Professor Janet.

A Manual of Practical Hygiene for Students, Physicians, and Health Officers. By CHARLES HARRINGTON, M.D., and M. W. RICHARDSON, M.D. Fourth edition. London: Henry Kimpton. Glasgow: Alexander Stenhouse. Pp. 850. Price 21*s.* net.

BEFORE his departure in 1908 for England, where he died unexpectedly, Dr. Harrington, the late professor of hygiene at Harvard University, had been preparing a revision of the "Practical Hygiene," of which he was the author, then in its third edition. His manuscript, as well as the remainder of the volume, have been revised and brought up to date by Dr. Mark Wyman Richardson, secretary to the State Board of Health of Massachusetts. The revision has been extensive, and Dr. Richardson has rendered a great service in undertaking it with such care and thoroughness. The present edition has lost nothing in clearness of exposition and excellent literary style; it is well printed, illustrated, and indexed. As a rule, text-books on public health matters which are published in the United States are used in this country principally for reference on matters in which American practice or theory differs from our own, but this volume makes a wider claim, as European and tropical work has been freely drawn upon, and the purely administrative questions, where each country has its own methods, find only a secondary place.

The first half of the volume deals with foods, air, soil, and water; the second principally with the hygiene of habitations, sewage disposal, disinfectants, military and naval hygiene, occupation and disease, insects in relation to human

disease, vital statistics, infection and immunity, vaccination and quarantine. The exposition of current theories of infection and immunity is particularly good, and in this, as in most sections of the book, the authors have made it their primary object to present a trustworthy review of facts gathered from all sources and of broad principles which should be accepted, while avoiding dogmatic statements on matters which remain controversial.

In any work of this nature there are necessarily subjects which individual readers would have wished to see amplified, and statements which seem to need qualification in the light of observations which are not referred to; but, as a whole, we have found very little to which serious exception could be taken. In view of the very full consideration given to milk in its relation to human tuberculosis, it is unfortunate that the volume was completed before the issue of the final report of the recent Royal Commission on Human and Animal Tuberculosis, which would have placed the authors on surer ground in dealing with the potential infectivity of tuberculosis of bovine origin. And for future editions, which are certain to be called for, we would suggest that in such matters as the methods of spread of small-pox, enteric fever, and scarlet fever greater use might be made of the publications of the Epidemiological Society of London (now continued in the Proceedings of the Royal Society of Medicine), which form so useful a compendium of the developments of preventive medicine, in its scientific aspects, in this country. We anticipate for this useful manual the increasing popularity which it fully deserves.

Manual of Toxicology. By R. A. WITTHAUS, A.M., M D., Professor of Chemistry, Toxicology, and Medical Jurisprudence in Cornell University. Reprinted from Witthaus and Becker's "Medical Jurisprudence, Forensic Medicine, and Toxicology" (second edition). London: Baillière, Tindall, and Cox. 1911. Pp. 1261. Price 30*s.* net.

THE general plan of this book is excellent, and the labour of reference is considerably lightened by the classification adopted. There is no preface, but the introductory chapter is an admirable essay upon the history of toxicology, at the end of which is a very complete bibliography of the subject, divided into—A, works exclusively toxicological: I., printed since 1850; II., between 1700 and 1850; III., before 1700. B, modern works on medical jurisprudence, &c., having reference to toxicology. The reader is next introduced to the difficulty of defining in succinct terms a poison. Dr. Witthaus distinguishes chemical agents which may cause death or injury by their destructive action upon the stomach as "corrosives." Clearing such harmful agents out of the way his definition of a poison becomes: "A poison is a substance which being in solution in, or acting chemically upon, the blood may cause death or serious bodily harm." A corrosive, however, is defined as "a substance capable of causing death or injury by its chemical action upon a tissue with which it comes in direct contact." The matter of definition does not rest so simply there, for obviously a substance, for example, hydrochloric acid, is a corrosive in strong form, whereas in dilute form it has no corrosive properties at all. Then what definition will include pathogenic bacteria which are not poisonous *per se*, but which are capable of elaborating poisons in a suitable soil? The best attempt at defining a poison is the French one quoted by the author, that "a poison is any substance which taken into the interior, or applied to the exterior of the body, is capable of causing death, or at least of destroying or seriously affecting health." The chapter on general toxicology begins thus with an interesting discussion, and the succeeding sections on causation, statistics, treatment, absorption, distribution, and elimination are most carefully done. The chapter on special toxicology includes the corrosives, the mineral acids, the alkalies, and the halogens.

The mineral poisons are first considered, of which arsenic, antimony, and phosphorus are examples; then the metallic poisons, such as barium, bismuth, copper, and zinc (chlorates are included in this category for a reason that is not quite clear, except it be that of convenience); then vegetable poisons (acids and alkaloidal); then animal poisons; and, finally, what the author calls synthetic poisons, which include carbon monoxide, chloroform, chloral, phenols, and nitrobenzene. Of course, certain poisons included in other sections also may be called synthetic, but he refers here to the poisonous organic substances which have no existence in nature or occur therein naturally only in minute quantity—substances which are the products of the chemical laboratory or of industrial processes. The care taken to record trustworthy methods of chemical detection and to indicate where the possibility of fallacies may arise is admirable. Such a single sentence as "we have failed to obtain this reaction by proceeding as directed above" (p. 908), is a mark of the author's precision and scientific attitude, and inspires confidence in the processes accepted. The experience of actual laboratory work at the bench is obviously of the utmost importance when that work is connected with the detection of poisons by chemical means.

The references to literature are very copious, and the index is a model of its kind. In particular will be appreciated the inclusion under the word "process" of the proper names of persons connected with various tests and analytical methods. The list, in alphabetical order, contains about 80 such names. The work is thorough-going, and already ranks high amongst the standard books of reference upon the subject.

The Ancient Egyptians and their Influence upon the Civilisation of Europe. (Harper's Library of Living Thought.) By G. ELLIOT SMITH, M.A., M.D., F.R.S., Professor of Anatomy in the University of Manchester, &c. With frontispiece and 15 figures in the text. London and New York: Harper and Brothers. 1911. Pp. 186. Price 2*s.* 6*d.* net.

THE impression left upon the mind of an attentive reader after the perusal of this book is likely to be that of astonishment—astonishment that so much new thought has been crowded into a small book of unpretentious exterior. The volumes of Harper's excellent series comprise semi-popular essays by a distinguished group of authors, and one expected to find no more, perhaps, than a clear and easily read account of the well-worn stock-in-trade of the Egyptologist. The present volume is, however, a fascinatingly daring excursion into the origin of the early population of the Nile Valley and its influences upon the ancient peoples of Asia, Africa, and Europe. Professor Elliot Smith in his nine years' familiarity with Egyptians, ancient and modern, had exceptional opportunities; and he was fortunate, too, that his graveside investigations were conducted with archæologists who, working with the best scientific methods, were able to provide him with what no other anthropologist in Egypt has hitherto had—viz., an accurate dating of all the material that he handled. Under these best of conditions he has examined a vast series of bodies representative of all periods of Egyptian history. It may be said truly that even the proto-Egyptian, the inhabitant of the Nile Valley who lived some 6000 years ago, has been made to parade all the details of his person, his clothing, his diet, and his whole life before us to-day. The author shows that, so far as our present knowledge goes, everything points to the fact that these people were indigenous to the Nile Valley, and that neither they nor their culture were imported from without. He depicts their life

in Egypt and Nubia and traces their kinsfolk in neighbouring lands; he shows how their arts evolved, till finally the tiny spark they kindled in a humble way lit up that great world-fire—the knowledge of metals—which, though it left the quiet dweller on the banks of the Nile comparatively undisturbed, set neighbouring hordes moving as waves across the mountains of Asia right to the western limits of Europe itself. The book, one feels, has somewhat the same tendency as the early evolution of Egyptian domestic arts of which it treats, for it seems to fire whole trains of thought, and to turn into a living thing what before was merely material for academic calisthenics.

LIBRARY TABLE.

Report on the Housing of Miners in Stirlingshire and Dumbartonshire. By JOHN C. MCVAIL, M.D. St. And., LL.D. Glasg., County Medical Officer. Glasgow: Robert Maclehose and Co., Limited. 1911.—The Local Government Board has recently called for reports from the medical officers of mining counties in Scotland on the housing of miners. A stranger to the subject might ask why the housing of miners should be specially investigated, but the answer is to be found in the conditions of the industry. Other workers, save agricultural labourers, are usually employed in or close to towns or cities where house accommodation is obtained in the ordinary way, the nature and cost of the accommodation being governed by the law of supply and demand. But coal-mines may be sunk far from any centre of population, and houses have then to be provided within a convenient distance of the shafts. This is seldom or never done by private enterprise, and a mining firm when opening a new colliery not near a town has usually to build a village for its employees. Much valuable, and at the same time interesting, information on the "Housing of Miners" has been embodied in this report which is published by the local county council at the request of the Local Government Board. Many defects are brought to notice, the commonest, most serious, and most flagrant nuisance that can be found in a village community, whether mining or ordinary, being the privy-ashpit system, which still prevails in so many places in Scotland, and which exists, though in very varying degrees, at most of the colliery rows in the counties to which Dr. McVail's report refers. Such privy middens, situated perhaps only 10 or 15 yards, occasionally much less, from dwelling-house doors and windows, are serious factors in the production and conveyance of disease, particularly by the breeding of flies, which, with their feet dipped in filth, invade the houses and infect food. Dogs and cats may rake amongst the refuse and afterwards play with children or contaminate food or milk that is standing exposed in the living room. Other points appearing to require attention are the provision of sculleries, indoor water-supply, water-closets, dustbins, washing houses, hot water-supply if practicable, coal cellars, paved footpaths, good roads, and garden plots. The maintenance of houses, roadways, drains, water-pipes, wells, sanitary conveniences, fences and drying greens in good order and repair is also urged. Truly such a deplorable condition of affairs as is shown in this report requires immediate remedy.

District Nursing. By MABEL JACQUES, Graduate of the Hospital of the University of Pennsylvania. With an introduction by JOHN H. PRYOR, M.D. 1911. New York: The Macmillan Company. Pp. 162. Price 4*s.* 6*d.* net.—It was a wealthy and philanthropic merchant of Liverpool, the writer tells us, who first conceived the idea of giving to the poor, in their own homes, the care of a trained nurse, so essential an adjunct in the saving of lives. As a result the first district or visiting nursing association was formed in Liverpool. Other cities quickly recognised the advantage of the movement and adopted it. District nursing, however, is no modern innovation, for in the early Christian era we know that there were certain women who visited from house to house caring for the sick. The need of a handbook dealing with the problems of organisation and expansion of district nursing is manifest at the present time, and this book indicates concisely the lines upon which district nursing should be based. Recent advances in charitable and social work make the district nurse an important factor in many new phases of philanthropic endeavour. In the campaign against tuberculosis and infectious diseases she will become more and more a necessary agency in preventive medicine. The time has now come when no public health department can be administered without the aid of a properly supervised and directed staff, comprising, amongst others, district visitors and district nurses. The writer has evidently studied her subject well, and this small handbook forms a welcome addition to a medical library.

Herbert Fry's Royal Guide to the London Charities. Edited by JOHN LANE. London: Chatto and Windus. 1912. Pp. 371. Price 1*s.* 6*d.*—This cheap and handy guide to the charities of London is now in its forty-eighth annual issue. The names of the various charities are given in alphabetical order, and brief particulars are supplied with regard to their aims and results, together with the dates of their foundation, the names of the chief officials, and their official addresses. There is also a classified index of institutions, which considerably enhances the value of the book. In an interesting preface on the charitable work of the year it is satisfactory to learn that for the support of the various charities a sum of no less than £30,000,000 sterling is held in investments, while large bequests are added year by year. Still, the fine sums available for charitable purposes do not adequately supply the needs of the institutions designed to ameliorate the undesirable social conditions which are a consequence of the growth of civilisation. The Insurance Act is causing much anxiety to our hospital managers, who fear that the provisions of the Act will affect adversely the contributions which they receive from employers of labour and from the better class of workmen, and, indeed, complaints that such is already occurring are now appearing in the daily press. As the editor of "Fry's Charities" points out, the public will be pursuing a singularly short-sighted policy should this prove to be the case, for "besides the direct treatment they" (the hospitals) "offer for disease and accidents, they act as schools of medical research and as unrivalled training grounds for the doctors and nurses, upon whose skill, patience, and genius the whole fabric of our medical world is built up."

JOURNALS AND MAGAZINES.

The Bristol Medico-Chirurgical Journal.—In the December issue of this magazine Mr. Charles A. Morton discusses the present position of the surgery of malignant growths, giving valuable advice as to the treatment of carcinoma of the rectum. Dr. J. A. Nixon calls attention to the spread of syphilis among members of a household by simple contagion, especially in the case of infants; and Dr. Newman Nield contributes some observations on tea poisoning, which he finds to be a not very rare condition. Dr. Carey Coombs writes on cardiac arrhythmia, with records of five cases, and Mr. G. Munro Smith on herpes and brachial neuritis, which may be different manifestations of the same affection.

The Birmingham Medical Review.—The two original articles which are contained in the December number of this review are devoted to diseases of children. Dr. Hugh

Thursfield] discusses errors and difficulties of diagnosis, including obscure cases of fever and of œdema, abdominal tumours and meningitis; and Mr. Seymour Barling deals with abdominal emergencies in childhood, especially with appendicitis and intussusception.

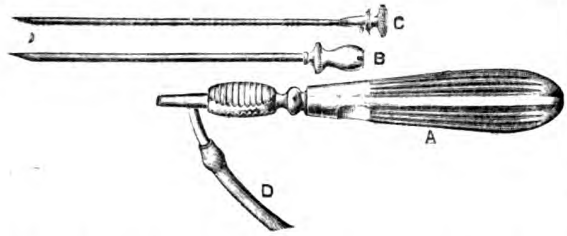
The Medical Chronicle.—Professor W. Stirling, writing in the December issue of this journal, makes a plea for the study of the history of medicine, and gives a brief summary of the chief events in this field, founded on the recently published work of Professor Neuburger, now translated into English. Dr. R. T. Williamson writes on the use of the spectroscope in medicine, and Mr. Robert Ollerenshaw discusses the causes and treatment of coxa vara.

The Edinburgh Medical Journal.—The late Professor Sir John Struthers made provision in his will for a lecture on anatomy to be delivered every third year in the Royal College of Surgeons of Edinburgh. The first of these lectures, delivered by Dr. Arthur Keith, is published in the current number of this journal. It deals with the progress of anatomy during Struthers's life and with the various men of note by whom advances were made. Dr. William Russell writes on the position of the stomach as a guide to pyloric or duodenal difficulty; and Dr. James Ritchie contributes a cautious paper on the subject of vaccine therapy, noting that practice in this field is in advance of actual knowledge. Mr. J. W. Struthers records a case of a Dermoid Cyst of the Neck, containing a number of curious soft white concretions.

New Inventions.

A CONVENIENT AND SIMPLE APPARATUS FOR THECAL (LUMBAR) PUNCTURE.

I FIND that the little apparatus, of which an illustration is here given, facilitates lumbar puncture and enables the operator to have greater control than if a syringe is used. Most authorities agree that suction should not be employed, therefore the syringe usually only serves as a handle. The syringe needle is usually unprovided with a stilette and the fluid is liable to become contaminated when dripping from the end of the needle after the syringe has been removed. A glass syringe is also liable to crack whilst being sterilised, and the process of sterilisation must take some time, as the syringe must be put into cold water which is brought up to



the boil and then of course must be allowed to cool down again before the syringe can be removed, if we wish to avoid the risk of cracking. This procedure takes at least a quarter of an hour. My little apparatus can be plunged straight into boiling water and taken out without any fear of injury. The cerebro-spinal fluid is conducted through the rubber tube D into a sterile test-tube, and thus there is practically no fear of contamination. If, after the puncture has been made, the fluid does not flow into the test-tube the holder A is removed and the stilette C passed down the needle B. I find, however, that it is only very occasionally that the stilette has to be used.

The apparatus was made for me by the Holborn Surgical Instrument Co., Limited, Holborn Circus, London, E.C.

H. WANSEY BAYLY, M.R.C.S. Eng., L.R.C.P. Lond.,
Clinical Pathologist, National Hospital for Paralysed and Epileptic, &c.
Upper Berkeley-street, W.

REPORT OF THE ASYLUMS COMMITTEE OF THE LONDON COUNTY COUNCIL FOR THE YEAR ENDING MARCH 31ST, 1911.

Statistics.

THE average daily numbers on the registers of the nine London County Council asylums and epileptic colony was 19,997. There were admitted during the year 3727 patients, and 1143 persons were discharged recovered. There were 1645 deaths. The patients for whom on Jan. 1st, 1911, the Council was primarily responsible to find accommodation was 20,158, this number including, besides the patients in the asylums, patients in other county and borough asylums under the committee's contracts or under arrangements made by the guardians. The accommodation available on Jan. 1st, 1910 (excluding Claybury Hall), was 19,867 beds, being an increase of 140 beds. The increase would have been greater but for a reduction in the accommodation for women effected at Hanwell Asylum through the disuse of some basement dormitories which had been adapted for occupation during a time of great pressure. The above number of patients is only a proportion of the total number coming under the purview of the London Poor-law authorities. It excludes patients in the Metropolitan Asylums Boards asylums, in workhouses, and those living with relatives and friends who are visited quarterly by the parish medical officer. This year's figures of the number of patients for whom the Council has been responsible show an increase of 244 on those for the previous year, and the rate of increase is again ascending, though the average rate of increase over the past 21 years appears to be declining.

Mental Hospital: Selection of Site.

Plans of a new asylum on the villa principle to be erected on the Horton Estate are still in preparation. A contract for the purchase for £10,000 of two freehold properties at Denmark Hill has been entered into, and is waiting the approval of the Secretary of State. The land, some 4½ acres in area, it is hoped will provide a satisfactory site for the mental hospital for 100 patients towards the cost of which Dr. Henry Maudsley in 1908 promised to contribute a sum of £30,000. It appears that the task of selecting a suitable site within four miles of Charing Cross has been particularly difficult. So far as it is possible to form an estimate of the cost of building and equipment, it is anticipated that this will amount to another £40,000.

Recurrent Insanity.[1]

Attention is drawn to a remarkable instance of a male patient admitted to Banstead Asylum on Feb. 13th, 1911, for the eighth time. This man is only 37 years old, and in addition to the periods passed at Banstead has been in Bethlem Royal Hospital, Ayrshire Asylum, the Kent County Asylum, Hanwell Asylum, and in a private licensed house. He has therefore been admitted to asylums on no less than 13 occasions. He married in 1903 and there are five children by the marriage, two males and three females (ages ranging from a little more than 1 year to 7 years), all of whom are now chargeable to the guardians of a London parish. The guardians' general relieving officer further states that the patient's wife is at present employed in service, but that the whole of the family have on and off been in receipt of indoor and outdoor relief since 1906.

These facts plainly indicate the great difficulty experienced in dealing with cases of recurrent insanity. Such cases, as the law stands at present, must be discharged as soon as they are apparently recovered, but it is often quite evident that with the removal of the fostering restraints of asylum life and the re-subjection of the patient to the stress and hardships of normal existence he will speedily break down. Moreover, as in the present instance, opportunity is afforded by the intervals of liberty for the propagation of children who must share in the mental and nervous instability of the parent, and who in their turn will probably swell the number of persons for whom asylum accommodation and care have to be provided.

Chapter XXIX. contains the report of the director of the Pathological Laboratory, Dr. F. W. Mott. It contains long lists of the papers issued and about to be issued.

THE LANCET.

LONDON: SATURDAY, JANUARY 13, 1912.

The National Insurance Act.

THE feeling among the medical profession with regard to the National Insurance Act has undergone no change during the week, unless it be that the general distrust of its provisions has increased. Many practitioners, the exact figure being rather uncertain, have signified public disapproval of the measure in response to questions submitted from two different sources. This was absolutely certain to be the result of the reference of any general question on the point to the whole constituency. For the future the feeling of the medical profession as a whole that the measure in its present form threatens sorely their professional and scientific status can be taken for granted, leaving all free to work towards a fair solution of the grave sociological difficulties that have been thrust upon us—and thrust upon us, we have always believed, with the best of intention towards mankind, if with small knowledge of medical circumstances.

Dr. LAURISTON SHAW addresses a letter to us this week in which he points out "the great need ..... to search out our points of agreement and work steadily together for their achievement. No sense of false pride or petty ambition must stand in the way of making use of every individual or institution that may be useful in securing our common aim." That is well said, but it is one thing to use an institution for a common aim and another to have a common aim in using an institution. The medical profession may easily endorse Dr. LAURISTON SHAW'S words, which have often appeared in our own columns, as to the potentialities for union contained in the British Medical Association, and yet may believe—as a large majority do—that the executive of the Association has not developed those potentialities at a critical point in medical history. It is for this reason, and for no other, that two movements have quickly sprung up to reinforce the Association, and as far as the Association is concerned its first task is to arrange that its members agree to live together in peace. On this matter sound advice is given them by Dr. CHARLES HARFORD in our columns this week. When the Association is a harmonious institution, it can be made use of in the way which Dr. LAURISTON SHAW advocates. Its task will be that of all of us—namely, to consider what are the regulations under which the Act, now the law of the land, can be so worked that medical service receives proper recognition, and that the public obtain benefits that are benefits in reality as well as benefits under an Act. It is expressly stated in the National Insurance Act that the Commissioners are to frame regulations in accordance with which the Local Insurance Committees will arrange with practitioners for the medical treatment of insured persons. These regulations will soon be forthcoming, and, as we said last week, union within our ranks must produce an impression upon those charged with framing them. It is these regulations which the medical profession must consider before deciding to take part in, or to stand aside from, the working of the Act, and what has to be done now is to prepare to meet the regulations in the spirit in which they are offered. The great corporations of the profession may here be able to play a part.

The Qualities of a Consultant.

THE principal teachers in any school of medicine would probably be nearly unanimous in any endeavour to select from among their students those who were most likely to achieve distinction in some branch of their future calling; but it may be doubted whether they would be equally in accord concerning the still more definite selection of those in whom this branch would be what is commonly known as consulting practice, whether generally medical or surgical, or confined within the narrower limits of a specialty. We should do no more than bare justice in admitting that the physicians and surgeons who, by common consent of the profession and of the public, have come to occupy what may be described as the highest pinnacles of consulting rank, have almost invariably been worthy of the confidence reposed in them; but we must equally admit that many others who, in the estimation of those best acquainted with their merits and attainments, have been at least equally worthy, have continuously failed to secure equal recognition, even though assisted by the ordinary opportunities of practice and teaching which are afforded by hospital appointments. Consideration of the causes alike of the successes and of the failures indicates that the circumstances of student life and of training may tend to the ultimate development of either issue, but the indication is a rough one. Is the successful consultant born with special qualifications in which the unsuccessful, although in some respects equally learned men, may be deficient; or do the two classes differ only in respect of the bearing upon their respective careers of the "time and chance that happeneth unto all"? In either case is it possible for the ambitious student so to regulate his studies or so to train his faculties that his chances in this particular competition may be improved? Are there any things which, with special reference to this object of ambition, he should strive to do, or any other things, perhaps more important still, which it is necessary for him to avoid? What, in short, are the special characteristics of consultants as a class, and in what manner, and to what degree, are these characteristics of a kind to admit of cultivation? The essential preliminaries of adequate professional knowledge, and for surgeons of adequate manipulative skill, must, of course, be assumed to exist as essential foundations in every case.

Taking, in the first instance, the needs of the practitioner by whom the consultant is called in, it may perhaps be assumed that one of the first of them is the support to be derived from the suggestion of a perfectly definite

course of procedure, founded upon an equally definite recognition of the true character of the departure from health. In some cases this character may be altogether obscure; in others it may appear to admit of one out of two or more solutions; and in all the first-aid asked for from the consultant is accuracy and completeness of diagnosis, or, in other words, not only the truth, but the whole truth, as far as it is ascertainable. The power of meeting this demand in a satisfactory manner is generally gained in one way—by the most minute possible study of symptoms (whether prominent or obscure) in the wards of a hospital, and by the most accurate possible comparison of these symptoms with the conditions which are disclosed either in the progress of the case towards recovery or ultimately in the post-mortem room. Such a comparison will usually be the more fruitful the less it is associated with hypothesis; the collection of observations should be large before any attempt is made to use them as a foundation for general deductions, lest these, being premature or erroneous, become distorting media for subsequent experience. No two cases of illness are alike, and the differential phenomena are those which it is of the greatest importance to observe and to remember. The consultant will constantly be called upon to deal with some apparently obvious malady *plus* x, and his power of determining the value of x will be the element on which his success will in all probability depend. But although assistance in the recondite may be what is generally sought from the consultant, the general practitioner and his patient may stand in need of reassurance where there seems no reasonable doubt of the diagnosis that has been made. It is often particularly difficult to follow the recommendation that the same course should be pursued that has been tried already, and that patience should be maintained in the face of the seeming failure of that course to remove the conditions. In this situation no one will be found more useful than that rather exceptional person, the consultant who is developing or who has developed from the general practitioner into the counsellor of general practitioners. It is true that throughout the busiest years of a successful career such a consultant may be in no close way in touch with the pathological side of hospital work. He must rely for his appreciation of the merits of many new therapeutic developments upon a much smaller personal experience than he who is in honorary charge of many beds in a great public institution; and his chances of having seen more than an isolated case of rare disease will not be so great. So far he must be at a disadvantage in comparison with the more usual type of consultant surgeon or physician; but, on the other hand, his great experience of the domestic treatment of disease may enable him more readily than one whose professional life is largely confined to the wards of his hospital and the walls of his consulting room to estimate how far in an uncertain case a certain treatment should still be persevered in; how far his brother practitioner is right in estimating the general condition of the patient to be no better or no worse over a long term of illness; and, lastly, how far details of nursing and treatment could be made less irksome. There is every room for such consultants, and the practical help which they can be to their fellow practitioners is truly great; with the present great developments of post-graduate work they may well become more numerous as the opportunities of renewing familiarity with the latest hospital experience grow more numerous and effective.

The main thoroughfares of diagnosis have been marked out by the footsteps of many generations of practitioners; and it is chiefly in the by-ways that opportunity can now be found for the display of exceptional acumen, or for the exercise of powers of observation trained to notice and to interpret the smallest departures from the customary course of things. There can, nevertheless, be no more fatal error than to allow the obvious to divert attention from the possibly obscure, or to lead to neglect of methods of observation not immediately suggested by the symptoms. The consultant can neglect nothing, and his most remarkable successes will often be the results of leaving no element of the case unexplored. This is the answer to all questions about the born capacity of the student to become a consultant, and as to the part played by luck in the attainment of success in such a position. The special characteristics of successful consultants are observation to see and judgment to weigh, and neither can be acquired save by industry. The most able student may start with the best chance of developing what may be termed the detective faculty, but unless his ability is reinforced by painstaking, minute, and laborious work in the wards his *flair* will avail him little. The general practitioner who has arrived at the position of a consultant owing to the gratifying fact that he becomes recognised, first in his own locality, and later through a more extensive range of country, as a man who is worth consulting, would never have arrived at that position had he not made extraordinarily good use of his opportunities when attached to a hospital, and could not maintain that position if he did not take all possible steps to keep himself abreast of both scientific and technical progress. A consultant is not a man who is ready to be consulted so much as a man whom his colleagues want to consult, a fact which sometimes escapes the attention of the laity.

The Uses of Medical Statistics.

THE limitations of statistics as applied to medical problems are well indicated in the following words of Mr. ARTHUR BOWLEY, the author of one of the best modern treatises on elementary statistics. Speaking of the want of recognition by statisticians themselves of the limitations of their work, he says: "At best they can measure only the numerical aspect of a phenomenon; while very often they must be content with measuring, not the facts they wish, but some allied quantity. We wish to know, for instance, the extent of poverty, its increase or diminution: poverty we cannot define or measure, and we cannot even count the number of the poor; all we can do is to state the number of officially recognised paupers, and add perhaps some estimates from private sources; but this gives us no clue to the intensity of poverty in individual cases. Or we wish to obtain statistics of health: all we can measure is the death-rate, and average length of life—very different

matters. The statistician's contribution to a sociological problem is only one of objective measurement, and this is frequently among the less important of the data; it is as necessary, however, to its solution as accurate measurements are for the construction of a building." Now this is quite true but the time has assuredly passed when it is necessary to justify the skilful employment of statistical methods for the elucidation of medical problems. Certain it is that without such help medicine, as a science, could never have achieved even its present degree of precision.

Our first text-books in the study of preventive medicine are the publications of the Registrar-General, with which the honoured name of WILLIAM FARR, the founder of vital statistics, must ever be identified. The value of the aid received from this source has been appreciated by all interested in the health and prosperity of our people, even where the qualified nature of that aid has been most clearly perceived. Half a century ago RUMSEY of Cheltenham emphasised the contention that as no public account is taken of the number and duration of the attacks of illness which shorten the effective life-time of the people, their condition in respect of health and vitality must be inferred solely from the number of lives lost; and there are facts in abundance to prove that the mere number of deaths in any locality bears no constant, or even approximate, ratio to the amount of unhealthiness actually existing there. Both the personal antecedents of the dead and the remote causes of death now generally escape notice, while the deaths of those who enter a district to die there belong rightfully to another district. Vast numbers succumb in our large hospitals, workhouses, and asylums whose diseases were not contracted in the places where they died, and who can scarcely be said to have lived there. Accordingly, the mere death-rate without the life-rate of the inhabitants, may, and often does, lead to fallacious conclusions as to local unhealthiness. Moreover, when the ages of a population are examined, the crude and hasty deductions from a general death-rate are not infrequently reversed. We doubt whether public opinion would at present support a proposal for the State registration of sickness of all kinds throughout the country. It would appear, however, that with medical officers everywhere responsible for the public health, with the army of parochial medical officers in attendance on the sick poor, and with the Central Department in Whitehall at their head, the setting on foot of such a project ought not to be impracticable; and it should follow that, given the coöperation of the registration staff at Somerset House, the cost of the supplemental service should not be prohibitive. Read in the light of codified information as to sickness incidence the figures relating to death-rates would assume a new importance; moreover, such a scheme of sickness registration might be highly valuable to public health authorities.

The opening years of the current decennium will be remarkable in the history of English vital statistics, as the period in which far-reaching changes have been inaugurated in the arrangement and publication of our national records of mortality and its causes—changes which must necessarily exert a profound effect on the future of State medicine as well as on the progress of sanitary science in this country. We have already noticed[1] the general tendency of the new arrangements adopted at Somerset House for the compilation of statistics, as set forth in the Registrar-General's report for 1909, but we feel it desirable again to allude to the matter for the information of those who are not familiar with the official document. Successive Registrars-General have deplored the discrepancies existing between the statistical data prepared by the local administrative authorities and those published by the Central Office. This anomaly is due to the fact that whereas, on the one hand, the local administrative authorities require statistics relating to urban or rural sanitary districts, on the other hand the tables published annually by the General Register Office relate not to administrative but to registration districts. But, unfortunately, the two types of districts are coextensive in very exceptional cases only. Hitherto the difficulties of general coördination of areas have proved insuperable, although something has already been achieved in this direction at the request of certain of the larger municipalities. It is satisfactory to learn that such of the difficulties as were removeable without alteration of statute law have now been surmounted, and, in view of the almost prohibitory character of those difficulties, the credit due to Mr. BERNARD MALLET is on that account proportionately increased. Accordingly, from the year 1911 onwards the returns of natality and of mortality will be arranged and published according to administrative areas, although the facts must still be collected for registration areas as heretofore. The substitution of the former for the latter of these areas renders desirable a still further correction of the returns. In order to ascertain even approximately the death-rate of a given place the deaths of strangers occurring therein must be excluded, the deaths of natives of the place that have been registered elsewhere being, of course, included. It may, indeed, reasonably be contended that in order to secure for medical statistics a reliable and permanent foundation the establishment of a national system of sickness registration is essential. As a first step the returns of sickness now required by the Local Government Board's orders from the hospital and Poor-law authorities may provisionally be tabulated and circulated, after expert analysis and criticism by the statisticians now dealing with the statutory records of birth and death.

FOREIGN UNIVERSITY INTELLIGENCE.—*Amsterdam:* Dr. K. Herman Bouman has been recognised as *privat-docent* of Diagnosis of Mental Diseases.—*Berlin:* The title of Professor has been granted to Dr. Julius Wohlgemuth, Oberarzt of the Frederick the Great Orphanage for Berlin at Rummelsburg; Dr. Erich Müller, surgeon to the Berlin and Brandenburg Cripples' Home; Dr. Konrad Biesalski, a laryngologist and otologist; Dr. Josef Herzfeld; Dr. Max Josph, an eminent dermatologist; and Dr. Ferdinand Hein, assistant in the University Anatomical Institute. —*Bonn:* The title of Professor has been granted to Dr. Karl Grube, well known for his researches on diabetes; Dr. Arthur Hübner, Oberarzt of the University Clinic for Nervous and Mental Diseases.

Annotations.

"Ne quid nimis."

THE SIGNIFICANCE OF THE THEORY OF HEREDITY IN OPHTHALMOLOGY.

THE influence of heredity in disease has long been an accepted fact, and many persons would assert that it has been even an exaggerated fact; but it is only comparatively recently that the hereditary transmission of physiological or pathological characteristics has been sufficiently investigated to afford some insight into the laws which govern the process. The experiments and deductions of Mendel, published in 1865, passed almost unnoticed until attention was drawn to them again in 1900 by de Vries. Since that date the subject has been assiduously worked at experimentally and theoretically by Professor Bateson and many others whose names are familiar to English readers. The Mendelian theory has not been accepted without cavil, and the criticisms of Professor Karl Pearson and others have but added to the impetus of the investigation. All, however, are agreed that the fundamental requirement is the accumulation of well-authenticated and scientifically certified material on the lines introduced by Sir Francis Galton. In no domain of pathology has the collection of illustrative examples been hitherto more productive than in ophthalmology. The types of ocular disease which display most clearly the influence of hereditary transmission are often more sharply defined and less obscured by the possibilities of extraneous influences than most other types of bodily ailments. Nowhere has the investigation been carried on with greater enthusiasm than in England, and the work of Mr. E. Nettleship in this domain stands out *facile princeps*. Professor Peters,[1] in his useful review of past work on heredity in relation to ophthalmology, gives Mr. Nettleship and his English colleagues due credit for their work on the various forms of hereditary cataract, hereditary night-blindness, and the inheritance of errors of refraction. But his paper will be specially welcomed for his review of the publications of German writers on the influence of heredity in congenital abnormalities of the eye. The rival theories of delayed or disordered development and intra-uterine inflammation as explanatory of congenital opacities of the cornea and anterior staphyloma have been warmly discussed in England and abroad, and his remarks on these subjects will be read with interest. Hereditary optic atrophy, an example of maternal transmission, receives less attention than it merits, and the late Mr. Ilbert Hancock's excellent paper is not mentioned. Congenital colour-blindness, too, another and better example of the same mode of transmission, is not dealt with. The author is on less solid foundations when he enters upon the discussion of the hereditary influence in senile cataract and concomitant squint. His remarks upon squint are well worthy of careful consideration, for if it should be proved that there are groups of cases of squint in which the hereditary principle is of prepotent influence it will not be without significance in the rational treatment of this disorder. If, for example, in such cases it should be proved that either congenital amblyopia or the loss of the power of fusing the images derived from the two eyes is a hereditary characteristic little hope of improvement by orthoptic treatment can be held out. The inheritance of optical defects of the eyes has hitherto thrown little light on the laws of heredity, chiefly owing to number and complexity of possible modifying factors. It is in examples of this nature that scientifically controlled statistical investigations are most needed, and such investigations could not be in better hands than Professor Karl Pearson's, who, with Miss Barrington, has already issued a valuable communication on the relative influence of heredity and environment on sight from the Galton Eugenics Laboratory.

DECEMBER AT HOME AND ABROAD.

THE last month of 1911 will rank as one of the mildest and wettest Decembers on record in this country, but both the high temperature and the rainfall were more marked in the south-western, southern, and south-eastern districts than in the north and north-west. There was, nevertheless, a fair amount of sunshine for the time of year. The mildness of the weather was very noticeable during the daytime, and particularly so after sunset. No frost except an occasional whitening of the ground occurred after the 7th or 8th. All the subsequent nights were very mild for the season in nearly all parts of the kingdom, many of them having a minimum temperature reading higher than that of an average December afternoon. Again and again the thermometer rose to 50° sometime between sunrise and sunset, while in the south and south-west that figure was reached or exceeded on a large majority of the days. At Torquay the mean maximum temperature was as high as 52°. In the metropolitan area the mean maximum at Westminster was 50·5°, this being more than a degree higher than that at Kew and Greenwich and as much as 3½° higher than at Hampstead. The nights were also rather milder at Westminster than in the suburbs, the mean minimum being 40 7°, against 39·5° at Hampstead and Greenwich and 39° at Kew. Very few days passed without bringing more or less rain. In the London district generally there were only seven or eight days without a measurable quantity. The aggregate was about 4 in. at Westminster and Greenwich and 4·5 in. at Kew and Hampstead. This, although more than twice the average, is very light compared with that which was common over a wide area in the south-west of England, where numerous localities reported a total exceeding 8 in. and some exceeding 10 in. Over these islands as a whole the sunshine showed little divergence from the normal, some places registering an excess and others a deficit. At some of the most rainy spots in the south-west of England, however, there was much more sunshine than is usual in December. At Torquay, for instance, where rain fell on 26 days and attained a total of 10·4 in. (6·5 in. above the average for December), the sun shone brilliantly during 73 hours, a figure 21 hours above the normal. In the more central parts of London the aggregate sunshine was much in excess of the average. At Westminster the average is only 13 hours, but last month the figure was 27 hours. In the metropolitan suburbs there was nearly as much sunshine as at many of the resorts on the south coast, the respective figures at Kew, Greenwich, and Hampstead being 42 hours, 41 hours, and 35 hours. In the City the value was lower, the total being no more than 10 hours. The City average for December is, however, only seven hours. At Westminster, Greenwich, and Hampstead there were 15 sunless days, and in the City 21, but at Kew there were only 11. The extreme south-west evidently benefited by the main wind current being from the south-westward, the smoke and dust being driven further to the east and north-east. In Switzerland and the central countries of the Continent the weather was mild for the time of year. Severe frost was unknown, and on some days the warmth was almost abnormal. The Riviera expects more or less rain in December, and on this occasion it had a fair amount during the first fortnight. The dry intervals were,

however, very pleasant, with a clear sky and a rather high temperature, and during the latter half of the month the weather was generally very fine, with the thermometer rising to nearly 60° during the day and remaining at a fairly high figure at night. As a rule the Riviera was almost 10° warmer than the south coast of England. Biarritz was not so sunny as the Riviera, and on no less than 13 days there was a measurable quantity of rain. The temperature, too, had a greater range than on the Riviera, many of the days being warmer and some considerably colder. In Italy the earlier half of the month was more or less rainy, some of the falls being heavy and prolonged and a cloudless sky the exception. Subsequently the general condition underwent great improvement, and although the temperature was rather lower and the wind at times stronger than on the sheltered Riviera, the weather was extremely agreeable as a whole. Frost occurred occasionally at some of the inland places in the north, and the nights over a large portion of the country were often colder than in England. The Algerian coast and the islands of the Mediterranean experienced generally fine weather, broken rarely by rain and sometimes by strong, squally winds. A temperature of 70° in the shade was not very uncommon during the early days, and even towards the end of the month the thermometer remained rather high. At Paris the weather was very little better than in London. Rain fell on as many as 22 days and yielded a total of 3·9 in., while the sun shone for no more than 47 hours, and on 16 days it was not seen at all. As in this country, the main wind current in France was between west and south-west, and its average velocity high.

DEFINITIONS OF VINEGAR.

THE desirability of having an official definition for vinegar was represented to the President of the Local Government Board by a deputation of the London and County Vinegar Brewers' Association, Limited, last autumn. The Assistant Secretary of the Board has now replied to the effect that while the Board has not at present any power to frame definitions of vinegar or artificial vinegar, it is desirable to state its views on the subject. These views are as follows:—

General Standard for Vinegar.

Vinegar is a liquid derived wholly from alcoholic and acetous fermentations; it shall contain not less than four grammes of acetic acid (CH_3COOH) in 100 cubic centimetres of vinegar; it shall not contain arsenic in amounts exceeding 0·0143 milligramme per 100 cubic centimetres of vinegar, nor any sulphuric or other mineral acid, lead or copper, nor shall it contain any foreign substance or colouring matter except caramel. Malt vinegar is derived wholly from malted barley or wholly from cereals, the starch of which has been saccharified by the diastase of malt. Artificial vinegar.—Artificial vinegar is any vinegar, or substitute for vinegar, containing, or derived from any preparation containing, any added acetic acid which is not wholly the product of alcoholic and subsequent acetous fermentation. It shall contain not less than four grammes of acetic acid (CH_3COOH) in 100 cubic centimetres of the artificial vinegar. It shall not contain arsenic in amounts exceeding 0·0143 milligramme per 100 cubic centimetres of artificial vinegar, nor any sulphuric or other mineral acid, lead or copper, nor shall it contain any foreign substance or colouring matter except caramel.

It cannot be doubted that these "views" will largely guide magistrates in cases in which a liquid described as vinegar is in dispute; just as the recommendations of the Departmental Committee upon Preservatives and Colouring Matters in Foods are regarded as authoritative, although they have no real statutory force. If the principle of definitions or standards is recognised by the Local Government Board, as seems to be the case in its recent communication on the vinegar question, great developments should follow. We realise that the general subject requires careful handling, but it would be more satisfactory if instead of official "views" or "recommendations" the statutes of the land provided a very definite line to go upon. As things are, the expression of "views" by the Local Government Board or the drawing up of "recommendations" by a Departmental Committee are apt to mislead our legal and judicial authorities besides the layman into thinking that these views and recommendations are sure ground upon which a decision will be based. The Local Government Board acknowledges that it has no power to frame definitions, but practically expresses an opinion as to what these definitions should be. That may be an awkward position for a Government department to take up.

THE MEDICAL DIRECTORY, 1912.

THE sixty-eighth annual issue of Messrs. J. and A. Churchill's Medical Directory[1] is now out. It shows a total increase of medical practitioners of 411 over last year, the entire number now being 41,053 disposed as follows: London 6480, provinces 17,735, Wales 1370, Scotland 3982, Ireland 2802, abroad 5364, Services 3320. As heretofore, the Directory contains an abstract of the principal laws affecting the medical profession, revised to date by Mr. W. Oliver Hodges, barrister-at-law. No reference, of course, could be made to the Insurance Act, as it was not an accomplished fact at the time of publication. There are the usual lists of the members of the General Medical Council and the Central Midwives Board, the holders of medical appointments to the King and the Royal Family, and of members of the medical profession on whom titular distinctions have been conferred. Mr. Norman Forbes contributes a gazetteer of the principal places of health resort, both British and foreign. Lists of officials of the Local Government Board and of the coroners of England and Wales, as well as of medical journals published in Great Britain, of Royal Commissions still sitting to deal with medical and public health questions, and of insurance offices follow. The Medical Directory fully maintains the reputation increasingly established through nearly seven decades.

A STUDY OF THE PAIN-SENSE IN THE PLEURAL MEMBRANES.

IT is well known that in some cases of pleurisy the pain is felt locally, while in others it may be referred, more especially in basal cases. An interesting experimental study of the pain-sense of the pleural membranes is recorded in the *Archives of Internal Medicine* of Dec. 15th, 1911, by Dr. Joseph A. Capps, of Chicago. It is known from anatomical investigations that the parietal pleura is innervated by the intercostal, sympathetic, and vagus nerves, while the visceral pleura is supplied by fibres from the pulmonary plexuses derived from the vagus and sympathetic nerves. The diaphragmatic pleura is supplied by the phrenics, and it has been shown by Cavalie that the last six intercostal nerves penetrate from 1 to 2 cm. into the margin of the diaphragm. Dr. Capps has studied the distribution of pain in 240 cases of pleurisy and pleuro-pneumonia, and in 75 cases of thoracocentesis he has attempted to explore the pleural surfaces with a long wire. In only 35 of these were the conditions favourable to free exploration, since a pleura covered with a thick exudate may obviously give no response to irritation. He finds that the visceral pleura is devoid of pain-sense. Irritation of the parietal pleura produces sharp pain that is accurately localised by the individual over the spot that is touched. It does not give rise to referred pain in the neck or in the abdomen. Irritation of the central portion of the diaphragm—viz., the part that is supplied by the phrenic nerve—sets up pain in the neck. Irritation of the periphery of the diaphragm—viz., the part supplied by the last six intercostal nerves—produces pain in the lower thorax, in the lumbar region, or in the abdomen The neck pain produced by irritation of the

[1] The Medical Directory, 1912. London: J. and A. Churchill. Pp. xliv. + 1964. Price 14s. net.

central part of the diaphragm is a true referred pain. The afferent impulses reach the spinal cord through the fibres of the phrenic nerve and excite painful impressions in the skin and superficial tissues supplied by the third and fourth spinal segments. The maximum point of pain has a marked tendency to appear along the ridge of the trapezius muscle. The pains elicited by irritation of the peripheral portions of the diaphragm are also referred pains, being distributed over the thorax and epigastrium in areas corresponding to the dorsal segments from the seventh to the twelfth. Both with these pains and with the neck pain there are associated cutaneous hyperæsthesia and hyperalgesia. The distribution of the referred pains varies with the part that is touched and with the degree of irritation. The more intense it is the greater the tendency of the pain to spread down over the lower abdomen. When the posterior part of the diaphragmatic pleura is irritated the pain is most marked in the lumbar region. Irritation of the pericardial pleura was followed by pain in the neck similar in character to that induced by irritation of the central portion of the diaphragm. It is interesting to note that in a series of cases of diaphragmatic pleurisy, in some of which the diagnosis was confirmed by necropsy, pain was present in the lower thorax, abdomen, or lumbar region in the great majority, while in about half of the cases there was pain in the neck. This affords an interesting illustration of the practical value of Dr. Capps's observations, which demonstrate clearly the origin and nature of pleural pain, and explain the difficulties which not infrequently arise in the diagnosis of conditions immediately above and below the diaphragm. Dr. Capps further states that he has a few observations which tend to show that the phrenic and intercostal nerves supply the peritoneal surface of the diaphragm with pain-sense as well as the pleural. His observations merit very careful consideration, and are an important contribution to the study of pleurisy.

THE TREATMENT OF BURNS.

IN the *International Journal of Surgery* Dr. J. F. Alexander has reported an interesting investigation of the treatment of burns. Having the unusual opportunity of treating simultaneously 27 cases of burns of the first, second, and third degrees he made a comparative test of five methods. All the patients were injured in trying to escape from the second floor of a burning building, and nearly all presented burns of the face, arms, and chest. Varying but very extensive areas of skin were involved; in four cases duodenal ulcers occurred; all the patients recovered. Seven cases of burns of the first, second, and third degree were treated by the boric acid solution bath, 5 of same degrees by picric acid solution, 5 of the second and third degree by carron oil, 5 of the second and third degree by unguentine, and 5 of the third degree by ichthyol ointment (48 grains of ichthyol added to 2 drachms of olive oil and incorporated with enough lanolin to make three ounces). The boric acid baths were given for two to six hours and repeated at intervals of two to six hours. A little experience showed that the parts should remain three hours in the bath. In the second group of cases gauze was saturated with picric acid solution and covered with oiled paper. The gauze was kept continuously moist and the dressing was renewed every second or third day. The ichthyol ointment was applied to the burns and covered with gauze and then with oiled paper. In all cases the lesions were thoroughly cleansed with soap and water before any dressing was applied. If there was considerable destruction of skin peroxide of hydrogen solution was then applied. If the dressing adhered to the raw surface a few drops of this solution allowed to fall on the gauze quickly dissolved the inspissated material and allowed easy and painless removal. All exfoliated epithelium was removed. In burns of the first degree the picric solution gave much the best results, and in burns of the second degree perfectly satisfactory results. In spite of extensive areas of skin involved no symptoms of picric acid poisoning were observed. In some cases the urine was darkened, but this condition soon cleared up under the administration of magnesium sulphate. The boric acid baths gave the best results in burns of the second degree and the ichthyol ointment in burns of the third degree.

CAVIARE.

IN spite of the esteem which caviare enjoys we have known it to be regarded by medical men as oily, indigestible, and unwholesome. We are inclined to dispute the accuracy of this view, having regard to the peculiar character of the constituents which the roe of the sturgeon contains. Numerous analyses have from time to time been made and the composition of caviare when averaged appears to be as follows:—Water, 50·92 per cent.; protein, 27·92 per cent.; fat, 13·59 per cent.; and mineral salts, 7·57 per cent. It differs sharply from the flesh of fish by containing a much larger quantity of fat. Moreover, this fat contains the peculiar oily phosphorus compound known as lecithin, which is a stimulant to metabolism affecting favourably the processes of nutrition. Caviare is, in fact, highly nutritive, and its digestibility has been determined, the time taken for its absorption being relatively short. If there is anything to be said unfavourably of caviare it is that its constituents err slightly on the side of "richness." The proteins of caviare contain a good deal of nuclein, and physiological experiments have shown that nuclein is a source of uric acid. The same is true, however, of sweetbread, kidney, *foie gras*, and these delicacies share with caviare the drawback of prohibition for persons of a gouty disposition. Like most foods with a peculiarly attractive and delicate flavour, caviare is expensive, and this fact holds any important consumption of it in check. It may be added, however, that caviare differs but a very little in composition from the much more familiar milt of the herring or the bloater roe. Bloater roe, like caviare, is rich in lecithin, though we are not prepared to assume that a measured course of bloater roe would have the same favourable effects in neurasthenia and in disturbances of nutrition generally as are obtained by administering the isolated fatty phosphorus compound.

THE RELATIONSHIP OF TUBERCULOSIS TO ACCIDENT AND INJURY.

IN another column we publish an address by Dr. W. C. Bosanquet on the relationship of tuberculosis to accident and injury. This is a subject which has claimed considerable attention during the past few years, mainly on account of its importance in connexion with the Workmen's Compensation Act. There is, unfortunately, a tendency on the part of workmen to try to attribute any illness to an accident, with the result that numerous cases are tried under arbitration which have no sound foundation in fact, and the time of the court is wasted, and the masters or the insurance companies are put to large needless expense. It is not denied that direct infection with tubercle bacilli may take place; numerous instances are on record. Further, many authorities maintain that tuberculosis of joints may follow injury, and Dr. Bosanquet quotes the French military surgeons who maintain that the majority of cases in their army in which amputation of the foot has to be carried out for tuberculous disease are attributable to old sprains. Instances of tuberculosis of the lungs following injury to the chest have been recorded, but in most of the cases it is not absolutely clear that the tuberculosis was

produced by the injury. It has also been suggested that in regard to pulmonary tuberculosis the accident may stir into activity a latent or quiescent lesion. To deny such a possibility would be difficult, but it is at least doubtful whether such a sequel could be proved. On the other hand, when active disease is present cases have been recorded in which an accident has apparently aggravated the disease. In a legal case, however, when damages are claimed on such a ground, the time that elapsed between the accident and the alleged aggravation would have an important bearing on the facts. Dr. Bosanquet remarks that if it were claimed that an injury and its resultant shock had so depressed a healthy person's resistance that he subsequently fell a victim to tuberculosis of the lungs considerable doubt would arise. We are acquainted with a case in which a widow of a deceased workman made a claim of this nature. The man sustained a Pott's fracture and died some nine months afterwards from pulmonary tuberculosis. For the woman it was suggested that the accident had so lowered the man's resisting power that he had become tuberculous. A medical assessor was sitting with the judge and the case was stopped without the defendants being called upon to reply. The occurrence of such legal cases by themselves cause the subject of "traumatic tuberculosis," as it is sometimes called, to be an important one, and many problems are involved which merit close attention and study.

THE CYTO-ARCHITECTONIC STRUCTURE OF THE CEREBRAL CORTEX [1]

WITHIN the last few years, owing largely to the researches of A. W. Campbell in this country, and of Brodmann and the Vogts in Germany, immense strides have been taken towards the perfecting of our knowledge of the structure of the cerebral cortex; and as this knowledge is sure to prove, indeed has already proved, to be of the first importance as a key to the pathology of certain mental and nervous states, it is well for the physician who is interested in the scientific side of his profession to have an intelligent idea of the progress that has already been made. It was known years ago, of course (since the researches of Bevan Lewis), that the cerebral cortex varied in thickness and in naked-eye and microscopical characters in different areas, but incompleteness of knowledge led invariably to confusion of thought until the subject was tackled afresh in its entirety, and with the aid of comparative anatomy, by the investigators whose names have been given above. Basing their work on the examination of transverse sections of the cortex from all its different parts, cut in series, they have definitely established the following first principle—viz, that the cerebral cortex is everywhere stratified, i.e., its cells are arranged in layers. In mammals the fundamental type of stratification is the six-layer type. By inversion, division, or diminution there may be derived from this type other varieties, to be referred to subsequently. The six layers, from without inwards, are described as (1) the zonal layer; (2) the external or outer granular layer; (3) the pyramidal layer; (4) the internal or inner granular layer; (5) the ganglionic layer; and (6) the multiform layer, according to the terms employed by Brodmann. Layers 1 and 6 are constant in man and the mammals generally, whereas layers 2 and 4 are very inconstant, and are frequently absent in man in certain areas of the cortex; layers 3 and 5 are also variable, but to a less extent than the preceding. Brodmann has also shown that this six-layer type may be present in the fœtus in parts of the cortex where at a later stage variation sets in, and that the rate of development of the six layers is not the same for all divisions of the cortex. The next point is that there are certain parts of the cortical surface where this six-layer type is not found, even in the embryo, constituting, roughly speaking, about one-tenth of the cerebral surface, nine-tenths being normally six-layered. Further, there are areas where during embryonic evolution the six-layered cortex becomes considerably modified, by augmentation or diminution of the number of layers. These areas take up about one-fourth of the cerebral superficies, and are of great importance, for they correspond to well-known physiological areas. Among them may be mentioned the visual area round the calcarine fissure in the occipital lobes, the motor area in front of the fissure of Rolando, certain parts of the frontal lobes, and the cortex of the island of Reil. In the calcarine area, for instance, the fourth layer is subdivided into three: in the motor area the fourth layer is awanting, while the giant pyramidal cells of Betz appear in the fifth layer, and so on. In this way it becomes readily understandable that the cerebral cortex can be mapped out into areas just like a geographical chart, each area corresponding to a particular type of cyto-architectonic arrangement. It is true, no doubt, that in the present state of our knowledge many of these areas are not of definite clinical interest, but some certainly are. Brodmann has distinguished 48 different regions, and it is a remarkably interesting fact that two of them are without homologue in the whole mammalian series—viz., the area corresponding to Broca's convolution and the area corresponding to the posterior end of the upper temporal convolution. These areas are a speciality, so to speak, of man, and naturally they may be taken to be of significance in connexion with the development of the faculty of speech. There is reason to suppose that not a few mental diseases have for their anatomical basis some disturbance, as yet not fully recognised, of the structure of the cortical stratification, and this is a pathological field on which investigation is only commencing. The belief, however, that in the prosecution of research along the lines sketched above, and based on the splendid work of Brodmann and others, results of far-reaching importance will sooner or later be attained, seems amply justified by the progress that has already been accomplished, of which the recent Goulstonian lectures of Dr. J. Shaw Bolton afford convincing evidence.[2]

[1] See, in particular, a recent paper by Dr. Ladame, of Geneva, in the *Revue Neurologique*, Nov. 30th, 1911.

THE MEDICAL LIBRARY ASSOCIATION OF AMERICA.

THE first two numbers of the *Bulletin of the Medical Library Association*, of America, edited by Dr. John Ruhräh and Miss M. C. Noyes, have been forwarded to us. This well-printed journal is worthy the consideration of the profession here, and of all those who take an interest in medical libraries, medical education, or the bibliography of medicine, surgery, and the kindred sciences. In a prefatory note the purposes of the *Bulletin* are briefly outlined as being primarily a means of communication between members of the association and a medium for the publication of lists of "wants" and of books and journals for exchange. In addition to this, at least one article on the work of medical libraries will be published in each issue of the journal. The first of these is from the accomplished pen of Dr. John H. Musser, president of the association. It is the record of his address, delivered at Atlantic city in May last. Dr. Musser reviews the work of the association and its finance, now flourishing under the management of an experienced treasurer. He further makes the satisfactory announcement that he was enabled, during the past twelvemonth, to hand to the association a card catalogue of the important books published in

[2] THE LANCET, vol. i., 1910, pp. 905, 980, 1047, 1077.

England, France, Germany, and Italy in the course of the past three years. "Members of the association," he continues, "can secure from the exchange titles of books on particular subjects in their respective languages." This is as it should be; a library association may be said to be justifying its existence when it can do this adequately. In the United States and Canada we gather that medical libraries are much of a size—that is to say, there are many medical collections scattered throughout those great countries which have all of them much the same equipment and resources. Here in Great Britain and Ireland matters are somewhat different. We have a few—a very few—preponderant libraries, and a number of small ones, and when the large libraries are asked to coöperate with the little ones cases arise in which, in vulgar parlance and so far as the large libraries are concerned, it is "all give and no take." The list of headings ("classification used at the Library of the College of Physicians, Philadelphia"), published in *Bulletin* No. 2, is valuable for purposes of reference. It is an ideal classification. That we on this side of the Atlantic use a somewhat simpler system is chiefly owing to the fact that we began the work of classifying many years ago—in the dark ages of library existence. Our system works well here, but the American system is none the less admirable.

THE PRESENT ASPECT OF SOME CANCER PROBLEMS.

THE opening lecture of the year at the Medical Graduates' College and Polyclinic was delivered by Dr. E. F. Bashford on Jan. 8th on the Present Aspects of Some Cancer Problems. In concluding, Dr. Bashford emphasised that up to the present all the methods which had been found efficacious in preventing the grafting and growth of carcinoma or sarcoma in normal animals had as yet no bearing whatsoever upon the treatment of the disease, but only upon the biology of cancer. All these methods, when applied to transplanted tumours already established, if they had any effect at all, produced inconstant results which could not be reproduced again at will. When applied to spontaneous cancer in mice they were as yet devoid of all therapeutic value, as the pictures exhibited showed. Similar remarks could also be applied to other suggested methods of treatment—e.g., by radium, which was found to cure certain transplanted tumours by Apolant in 1904, and by Bashford, Murray, and Cramer in 1905. This effect was obtained only for certain tumour strains and was not constantly obtained even in the same strain at different times. Toxic doses of adrenalin had been shown in 1905 by the latter authors to assist in the disappearance of transplanted tumours, and Reichert in 1909 had confirmed this observation; adrenalin was, however, as inconstant and unreliable as radium. Sera of different kinds had been found completely inactive. The possibilities of active immunisation lay entirely in the future, and mainly for this reason, that when healing occurred spontaneously, either in a transplanted or in a spontaneous tumour, whether a change in the animal was of moment or not, it had been satisfactorily demonstrated that local conditions obtaining in the tumour cells themselves played the determining rôle. Their elucidation was necessary if spontaneous healing was to be imitated experimentally. The extreme rarity of complete healing of spontaneous tumours required to be borne in mind in estimating both the difficulties of the investigation and its therapeutical possibilities. On a basis of the careful following of the clinical course of almost 1000 spontaneous tumours in mice, Dr. Bashford estimated attempts at healing, either partial or complete, at not so high as 1 per cent. In conclusion, he referred to some highly suggestive experiments carried out by A. von Wassermann in Berlin.

Dr. Bashford said: I returned from Berlin yesterday where I have been for some time on matters unconnected with cancer, but being there I considered it my duty to obtain personal experience of Wassermann's work, and he generously placed all his knowledge at my disposal. By following a line of thought inseparably associated with the name of my respected teacher—Ehrlich—Wassermann conceived the possibility of making a direct attack upon the cancer cell by approaching it through the blood stream. His reasoning was that since the cancer cells were growing rapidly their oxygen requirement would be very great—i.e., in Ehrlich's sense there would be a differential between the avidity for oxygen of the tumour cells and the rest of the cells of the body. The tumours would be very susceptible to anything which interfered with their supply of oxygen. Without going into details the problem resolved itself into how to convey selenium not only into the neighbourhood of the cell, but, if possible, also into the cell substance. After testing some hundreds of preparations it was found possible to do this by means of eosin. The idea of handing on such an element as selenium by means of such a dye as eosin could hardly have occurred to one not trained in the Ehrlich school as Wassermann has been, and its fruitfulness was at once seen. The pink solution of the eosin-selenium combination when injected in the venous system of a tumour-mouse at once colours the skin pink, but in a few hours the colour disappears from the surface of the body, and if the mouse is killed and examined it is found that the tumour alone is deeply stained. After repeated injection, if the mouse survive the tumour disappears in accordance with an orderly sequence of events. By this method Wassermann has achieved more than can be claimed for any of the other methods I have described to you, since the result is both constant—i.e., under given conditions can always be obtained—and equally efficacious when tested on spontaneous tumours. But the method is only in its infancy, and we know how radium and other agents have in the past had the aggravating property of giving the best results at the beginning. Still, it would be unfair of me to offer any criticism at this stage, for Wassermann has himself published ample warning. He states that the substance is a dangerous poison. In an experiment Wassermann and Keysser performed for my instruction it killed four out of six mice, but of the two that survived both were cured, and this is the inevitable result if the mice can withstand the treatment. The substance is difficult to prepare and its exact constitution is not yet known, but as in the case of all purely chemical problems these are difficulties laboratory skill and patience will speedily overcome. Wassermann does not claim to have found a cure for cancer, but merely to have demonstrated that what was previously deemed impossible has been demonstrated as a fact—viz., that a chemical substance can be prepared which when injected into the blood stream has an elective affinity for tumour cells injuring and killing them while sparing the rest of the body. To all who can appreciate the significance of this step forwards it will appear that the possibilities of following up this clue open up one of the most hopeful prospects as regards our ultimately being able to treat the disease in man. Great patience will, however, be necessary, new knowledge of the cancer cell and new applications of biological methods may be required to heighten the susceptibility of the tumour cells to interference with the oxygen supply. What is efficacious in a mouse may not work in a rat, rabbit, dog, or cow, and in any case no application to man will be possible until a less toxic preparation can be produced, and a more extensive application has been made to spontaneous tumours of varied nature. Nevertheless, I feel bound to admit the importance attaching to Wassermann's experiments.

THE annual dinner and smoking concert of the South Wales Mounted Brigade Field Ambulance, R.A.M.C. (T.), took place recently at the Imperial Café, Hereford. Lieutenant-Colonel J. R. I. Raywood, the officer commanding, presided, and was supported by Captain Griffiths, R.A.M.C., on a thoroughly successful occasion. The work done by the unit in 1911 included an Easter camp at Ledbury, annual brigade training at Builth, and camp at Carnarvon. Three officers and 18 non-commissioned officers and men attended special courses at the Royal Army Medical Corps School of Instruction, Cardiff, and one officer and three men the Army Service Corps Depôt, Manchester. The strength of the unit is 115 non-commissioned officers and men and four officers. The training this year is at Porthcawl, South Wales.

THE PRESENT POSITION OF ANTI-MALARIAL METHODS IN INDIA.

IT has been recently stated that malaria causes more sickness and mortality in India than any other disease. The late Sanitary Commissioner with the Government of India calculated that more than a million deaths from endemic malaria occur in ordinary years, and that in particular years when malaria epidemics arise this mortality may be well-nigh doubled. As malaria is not usually a very fatal disease this enormous number of deaths must represent a vast amount of non-fatal sickness, giving rise to a great deal of suffering and resulting in considerable economic loss to the State.

Efforts in the Past.

In the past strenuous efforts have not been wanting to prevent the ravages of this formidable malady in India, reliance having been placed hitherto mainly upon the use of quinine both as a curative and as a prophylactic agent. Under Government auspices the cultivation of the cinchona plant has been greatly extended, and this has led to a large reduction in the price of quinine, which has thus now become obtainable even by the poorest classes in India. But it is well known how difficult it is to secure the regular and systematic taking of quinine by natives, and even by Europeans sometimes, in malarious districts. It is true that better results are found in prisons and other institutions, or among bodies of men under discipline, but these form only a fraction of the great number that need protection against this disease. It may, therefore, be said generally that notwithstanding the efforts which have been made in the past, with the help of quinine, the ravages of malaria in India have not been materially reduced or greatly alleviated.

Anti-mosquito Measures.

It is now about 14 years since Sir Ronald Ross, then an officer of the Indian Medical Service, working at Secunderabad, discovered the mode in which the protozoal parasite of malaria is transmitted from man to man through the agency of a species of water-breeding mosquitoes, the Anophelinæ; and this discovery at once suggested new methods of fighting the disease by measures to extirpate the incriminated mosquitoes and destroy their breeding-places. Major works for draining swampy land and marshes and minor operations for filling up pools and hollows or coating the surface of the standing water with crude oil were strongly advocated. But these proposals did not apparently find much favour at the time in official circles, objections being raised mainly on the score of the great expense which the measures would entail, and also on the ground of their impracticability and unsuitability to the special circumstances of a country like India.

In 1901 an experimental trial of the new methods was initiated at Mian Mir, but in 1909 a Government Commission, which had been appointed to investigate the results, gave an unfavourable report upon them. This test, however, in the opinion of Sir Ronald Ross, was hardly a fair one, and in public he has characterised it as having been "ill-judged and ill-conducted." It is beyond doubt that the Mian Mir experiment was the means of hindering, for a time at least, the adoption of mosquito destruction as an important antimalarial measure in India.

Imperial Malaria Conference.

The new methods have already been successfully tried in some other countries, and the facts associated with these instances were brought to the notice of the Indian Government, which in 1909 summoned an Imperial Malaria Conference to meet at Simla, where after due discussion a series of recommendations was passed. These included the need for establishing a permanent organisation to direct a campaign against malaria in India and to undertake scientific investigations; the advisability of carrying out measures for the extirpation of mosquitoes; the continuation of efforts to secure a wide distribution of quinine in the affected districts; and lastly, the need for educating the native population in the main facts about malaria. Since this conference was held a change has seemingly taken place in the official attitude towards the modern methods of fighting malaria. This is noticeable in the address which the present Director-General of the Indian Medical Service, Sir C. P. Lukis, K.C.S.I., gave at Bombay in November last before a malaria conference and in other recent official statements. A central scientific committee for the study of malaria in India, with provincial committees and a general committee, have now been set up to organise the anti-malarial campaign. In order to provide the necessary special training in modern methods of malarial research a central malarial bureau has been established at Kasauli, with a museum, laboratory, and reference library, and with a new journal called *Paludism* as its organ, to spread the knowledge acquired by the bureau and to publish reports and other useful information. At Amritsar also an institute has been founded and a laboratory opened for special malarial research and for purposes of instruction. Already 48 officers and subordinates have gone through special courses of training, and at the present time most, if not all, of the Indian provinces are provided with the services of expert officers, who are aided by an adequate staff devoting their whole time to anti-malarial work.

Measures now being taken in Various Provinces.

Sir C. P. Lukis furnished a statement to the Imperial Legislative Council at Simla last September, in which he summarised the measures in progress against malaria in the provinces. In Madras Presidency, for example, in addition to the appointment of a special staff under expert direction, the following practical measures are being carried out—viz., the introduction of effective drainage in different places, the filling up of useless ponds and pits, the prohibition of "wet cultivation" in the proximity of dwellings, the destruction of mosquito larvæ by petrolage, along with the free distribution of quinine. Almost identical measures are being taken in the Presidency of Bengal, where, in addition, an important proposal from the local government is under consideration for a special engineering establishment to deal with drainage schemes. As a further indication of the change which has occurred in the official attitude towards mosquito reduction we may mention the case of the city of Bombay, where malaria has been of late years increasing in amount, and where in consequence Dr. C. A. Bentley, a well-known expert, has been investigating the causes of this increase. In his report he pointed out that the breeding-places of the anophelines must be destroyed, and it is gratifying to learn that the provincial government has intimated to the municipality that if vigorous measures are taken by them on the lines suggested by Dr. Bentley they will be assisted with a grant of 1 lakh of rupees from provincial revenues.

The Punjab is a special sufferer from epidemics of malaria, and Major S. R. Christophers, I.M.S., a member of the Central Committee for the Study of Malaria in India, who has made inquiry into their cause, has pointed to the flooding of certain areas, and especially of low-lying land near the banks of rivers, as an important factor in the production of these epidemics. Works for the prevention and control of these floods are recommended, and are at present under the consideration of the Government. Lastly, we may draw attention to an important statement made by Sir C. P. Lukis to the effect that in the fiscal year of 1910–11 a special non-recurring grant of no less than 57 lakhs of rupees was made from Imperial revenues for expenditure, chiefly on drainage schemes likely to prove of benefit to towns affected by malaria. The above gives a summary of much that is already known to our readers, while in THE LANCET of Oct. 17th, 1911, we drew attention to the Indian Research Fund, one of the objects of which is to provide means for carrying out various methods by which the people of India may be educated in subjects of elementary hygiene and domestic sanitation, and in the knowledge of how they may best protect themselves against malaria and other diseases.

New Era Inaugurated.

From what we have said it is apparent that at no previous time has so much been done to check the disease and to utilise the most modern methods for reducing the widespread ravages of malaria in India. A new era has thus been inaugurated, the prophylaxis by means of quinine being now reinforced by much-needed major and minor works instituted with a view of reducing mosquitoes and destroying their breeding places. These efforts, we believe, must lead to a marked diminution of the disease, and as a result should lead to a decrease in the human suffering and economic loss which have for so long afflicted our Indian Empire.

MEDICINE AND THE LAW.

Death from a Wasp's Sting under the Workmen's Compensation Act.

A CLAIM for compensation by a widow named Potter, in which Judge Mulligan, K.C., gave judgment recently in the Downham county court, gave a fresh illustration of the difficulty of determining what constitutes an accident arising "out of and in the course of" a workman's employment. The deceased husband of the applicant was engaged as a waiter at an entertainment following a wedding in a country district, and on the day following the wedding a dinner was being prepared for the villagers, the deceased man Potter being in the service of the caterer, Mr. C. W. Smith, who supplied the refreshments. The remains of champagne in the emptied bottles, and of food provided for the first day, had attracted a number of wasps, and on the second day when Potter with his companions had stopped working in order to eat their luncheons in the tent, he suddenly exclaimed, "I am done," and removed a dead wasp from his tongue. He had been stung and he died an hour later, a post-mortem examination, of which evidence was given at the inquest, showing that he had suffered from valvular disease of the heart. The verdict of the coroner's jury, which was put in as evidence on the application of the widow for compensation, ascribed death to "Heart failure caused by shock consequent upon the sting of a wasp on the tongue—Accidental death." The county court judge held that death was due to the accident of the sting and that "the fact that the man's condition predisposed him to succumb to such an accident was immaterial, and the medical alibi—valvular disease of the heart—in this case could not prevail." He was also satisfied that the accident occurred in the course of the employment of the deceased. This left the question whether it arose out of that employment, and as to that he had to ask himself whether the accident resulted from a risk reasonably incidental to the employment. He found as to this as a matter of fact that the deceased, by reason of the work that he had to perform in the tent, was exposed to an extraordinary and peculiar danger of being stung by wasps, and that his death was the result of a risk reasonably and peculiarly incidental to his employment. He pointed out that the question was one to be decided upon the facts of the particular case before him, and quoted from the Lord Chancellor's judgment in the case of Kitchenham (1911, Appeal Cases, 417) to the effect that the words "out of and in the course of the workman's employment" admit of inexhaustible varieties of application according to the nature of the employment and the character of the facts proved. The Lord Chancellor said with regard to this "the facts in different cases are infinitely different, and if we (the House of Lords) were upon each argument to discuss them and to differentiate one from another, judgments of courts of law would be interminable and would lead rather to confusion than to enlightenment." The case of Potter *v.* Smith would appear to be one likely to lead to an appeal, but if the man was provided with food by his employers as one of the conditions of his service, and it was food which, owing to circumstances, contained wasps, or if he was expected to eat his luncheon in a place infested by wasps, it would seem not unreasonable to say that the accident of being stung arose out of the employment. The expression, however, used by Judge Mulligan and quoted above, "a medical alibi," as applied to the proof of the existence of valvular disease of the heart is not easy to understand. An alibi that fails is usually an incident in a trial discreditable to the witnesses who appear in support of it. There certainly, however, can be nothing discreditable in giving evidence of the presence of a disease without which death would not have taken place, or in an advocate, as distinct from the medical witnesses, laying stress upon it on behalf of his client. Not to prove its existence, either at the inquest following the death or in an inquiry such as that held in the county court, would be to suppress evidence of an essential fact connecting the death with the accident of the sting.

The Death of Mr. Terence Barclay.

It has been stated in the newspapers that an inquest has not been considered necessary in the case of Mr. Terence Barclay, who was mauled by a lion cub kept as a pet, dying from subsequent blood poisoning. The occurrence was of a very unusual and extremely tragic nature, and the relatives of the deceased are entitled to warm sympathy in their loss. To them, no doubt, the avoidance of an inquest was a welcome relief from attendance at an inquiry which would have increased their pain. At the same time, we are puzzled as to why an inquest should have been dispensed with in consequence, according to the information before us, of the acceptance of a certificate of the cause of death. No doubt the medical man or medical men who attended the deceased after he received his wounds were able to state accurately in a certificate the cause of his death, and we are not aware that there could be any objection to this being done. It, however, could not by itself free the coroner from the obligation to hold an inquest where there is reasonable cause to suspect that a violent or an unnatural death has occurred, and it can hardly be suggested that the death of Mr. Barclay, the main facts attending which have been described in the public press too fully to need recapitulation, was in the ordinary acceptance of the term a natural one. On the other hand, so far as the reported facts are concerned, the case was one which on public grounds might well have been inquired into in some detail. The keeping of dangerous wild animals in the grounds of a country gentleman's house cannot be a safe proceeding unless extreme care is exercised to ensure that the confinement imposed is such as to preclude the possibility of escape, and to prevent as far as possible danger to their immediate owners and to others. An inquest is not held with a view only to the punishment of those, if any, who may be criminally responsible for a death, but in order that by a full inquiry into unnatural deaths the public may be protected or reassured according to the circumstances of the individual case. The death to which we have referred will, however, no doubt, serve as a warning to those who wish to rear young lions, or other naturally fierce animals, of the danger of so doing. The gradual growth of such beasts may disguise the development of their adult tendencies and of their mature physical strength, but those tendencies will probably supervene, and combined with a strength of which neither they nor their masters may be aware, will one day render them dangerous possessions.

VITAL STATISTICS.

HEALTH OF ENGLISH TOWNS.

IN 77 of the largest English towns, having an estimated population of 16,157,797 persons in the middle of the year 1911, 6673 births and 4881 deaths were registered during the week ending Dec. 30th, 1911. The annual rate of mortality in these towns, which had been 15·2, 16·4, and 15·9 per 1000 in the three preceding weeks, declined to 15·7 in the week under notice. During the 13 weeks of the fourth quarter of last year the mean annual rate of mortality in these towns averaged 14·7 per 1000, and was 0·4 per 1000 in excess of that recorded in London during the same period. The annual death-rates in the 77 towns in the week under notice ranged from 4·9 in Hornsey, 7·7 in Hastings and in Halifax, 9·1 in Ipswich, and 10·9 in Rhondda and in Merthyr Tydfil, to 21·6 in Bootle, 22·0 in Burnley, 22·2 in Bury, and 23·1 in St. Helens.

The 4881 deaths from all causes in the 77 towns were 30 fewer than the number in the previous week, and included 290 which were referred to the principal epidemic diseases, against 305 and 291 in the two preceding weeks. Of these 290 deaths, 76 resulted from whooping-cough, 66 from measles, 54 from infantile diarrhœa, 53 from diphtheria, 21 from enteric fever, and 20 from scarlet fever, but not one from small-pox. The mean annual death-rate from these diseases last week was equal to 0·9 per 1000, against 1·0 and 0·9 in the two preceding weeks.

The deaths attributed to whooping-cough, which had steadily increased from 16 to 52 in the eight preceding weeks, further rose to 76 in the week under notice, and caused the highest annual death-rates of 1·1 in Birmingham, 1·6 in St. Helens, 1·7 in Derby, 1·9 in Great Yarmouth, and 2·8 in Walsall. The deaths referred to measles, which had been 52, 71, and 70 in the three preceding weeks, declined to 66 in the week mentioned; the highest death-rates from

this disease were 1·3 in Norwich and in Stoke-on-Trent, 2·0 in Nottingham, and 3·9 in Burnley. The 54 fatal cases of infantile diarrhœa were 1 fewer than the number in the preceding week, and included 18 in London and its suburban districts, 5 in Birmingham, 4 in Liverpool, and 4 in Manchester. The deaths attributed to diphtheria, which had risen from 57 to 67 in the four preceding weeks, declined to 53 during the week, and of this number 17 were registered in London and its suburban districts, 4 in Leeds, 3 in Wallasey, and 3 in Manchester. The deaths referred to enteric fever numbered 21, being 1 less than the average in the seven preceding weeks; 4 deaths were recorded in Leicester, 3 in Sheffield, 2 in London, and 2 in Hull. The fatal cases of scarlet fever, which had been 27 and 25 in the two preceding weeks, further fell last week to 20, and included 3 in London, and 2 each in Norwich, Aston Manor, Coventry, Liverpool, and Bradford.

The number of scarlet fever patients under treatment in the Metropolitan Asylums and in the London Fever Hospital, which had steadily decreased from 2213 to 1912 during the six preceding weeks, were equal to 1914 on Dec. 30th; 162 new cases of this disease were admitted to these institutions during the week, against 241, 224, and 182 in the three preceding weeks. These hospitals also contained on the date mentioned 1308 cases of diphtheria, 233 of whooping-cough, 105 of measles, and 77 of enteric fever, but not one case of small-pox. The 1325 deaths from all causes in London were 38 fewer than the number in the preceding week, and included 332, which were referred to diseases of the respiratory system, against numbers steadily increasing from 170 to 390 in the eight preceding weeks.

The deaths attributed to different forms of violence in the 77 towns, which had declined from 201 to 185 in the three preceding weeks, further fell to 170 in the week under notice, and 461 inquest cases were registered. The causes of 60, or 1·2 per cent., of the deaths registered in the 77 towns last week were not certified either by a registered medical practitioner or by a coroner after inquest. All the causes of death were duly certified in Manchester, Leeds, Bristol, West Ham, Bradford, Newcastle-on-Tyne, Nottingham, and in 48 other smaller towns. The 60 uncertified causes of death last week included 9 in Birmingham, 8 in Liverpool, 6 in Gateshead, 4 in Preston, and 3 each in London, King's Norton, St. Helens, and Rochdale.

From the commencement of the current year the Registrar-General's weekly returns will relate to the 94 largest towns of England and Wales which at the recent Census contained populations exceeding 50,000 persons. The aggregate population of these towns in the middle of the present year is estimated to be 17,559,219 persons. During the week ending Jan. 6th 8657 births and 5152 deaths were registered in these towns. The deaths were equal to an annual rate of mortality of 15·3 per 1000, against 16·4, 15·9, and 15·7 in the former 77 towns during the three preceding weeks. The annual death-rates in the several towns ranged from 4·9 in Eastbourne, 5·2 in Hastings, 8·0 in Wakefield, 8·3 in Wimbledon, and 8·8 in Ilford, in Oxford, in Devonport, and in Middlesbrough to 19·5 in York, 19·7 in Enfield, 20·0 in Stoke-on-Trent, 20·7 in St. Helens, 21·3 in Preston, and 23·3 in Dudley.

The 5152 deaths from all causes in the 94 towns last week included 313 which were referred to the principal epidemic diseases, and of these 83 resulted from measles, 78 from whooping-cough, 57 from infantile diarrhœa, 49 from diphtheria, 24 from enteric fever, and 22 from scarlet fever, but not one from small-pox. The mean annual death-rate from these diseases last week did not exceed 0·9 per 1000 of the estimated population, and was equal to the rate in the 77 towns during the two preceding weeks. The highest annual death-rates from measles were 1·3 in Swansea, 1·4 in Warrington, 1·5 in West Bromwich, 1·8 in Salford, and 3·0 in Norwich; from whooping-cough, 1·2 in Newport (Mon.), 1·8 in Great Yarmouth, 1·9 in Dewsbury, 2·1 in St. Helens, and 3·9 in Walsall; and from infantile diarrhœa, 1·1 in Stoke-on-Trent and 1·2 in Hornsey. The 49 deaths attributed to diphtheria included 12 in London and its 14 suburban districts, 5 in Leeds, and 3 in Bristol.

The number of scarlet fever patients under treatment in the Metropolitan Asylums and in the London Fever Hospital, which had steadily decreased from 2213 to 1914 in the seven preceding weeks, had further declined to 1845 on Saturday last; 193 new cases of this disease were admitted to these institutions during the week, against 224, 182, and 162 in the three preceding weeks. These hospitals also contained on Saturday last 1279 cases of diphtheria, 255 of whooping-cough, 116 of measles, and 65 cases of enteric fever, but not one of small-pox. The 1347 deaths from all causes registered in London during the week under notice were 24 in excess of the number in the preceding week, and were equal to an annual death-rate of 15·5 per 1000. During the 13 weeks of the fourth quarter of last year the average annual death-rate in London did not exceed 14·3 per 1000, and was 0·4 per 1000 below that recorded during the same period in the 77 large English towns. Of the 1347 deaths in London last week, 21 were attributed to measles, 17 to infantile diarrhœa, 14 to whooping-cough, 6 to diphtheria, 5 to enteric fever, and 3 to scarlet fever. The deaths referred to diseases of the respiratory system, which had been 390 and 332 in the two preceding weeks, rose again to 382 last week, and were 93 in excess of the number in the corresponding week of last year.

Of the 5152 deaths in the 94 large towns last week 194 were attributed to different forms of violence, and 455 were the subject of coroners' inquests. The causes of 45, or 0·9 per cent., of the deaths registered last week were not certified either by a registered medical practitioner or by a coroner after inquest. All the causes of death were duly certified in Sheffield, Leeds, Bristol, West Ham, Bradford, Hull, Newcastle-on-Tyne, Nottingham, and in 69 other smaller towns. The 45 uncertified causes of death last week included 10 in Birmingham, 10 in Liverpool, 4 in Gateshead, and 3 in Darlington.

HEALTH OF SCOTCH TOWNS.

In Glasgow 399 births and 274 deaths were registered during the week ending Dec. 30th, 1911. The deaths were 1 in excess of the number recorded in the previous week, and were equal to an annual rate of 18·2 per 1000, against 18·4 and 18·2 in the two preceding weeks. During the 13 weeks of the fourth quarter of 1911 the annual death-rate in Glasgow averaged 17·9 per 1000, and was 3·6 per 1000 above the rate recorded in London during the same period.

The 274 deaths from all causes during the week mentioned included 36 which were referred to the principal epidemic diseases, against 31 and 38 in the two preceding weeks. Of these 36 deaths, 17 resulted from measles, 5 from diphtheria, 5 from diarrhœal diseases, 4 from whooping-cough, 3 from scarlet fever, and 2 from enteric fever, but not one from small-pox; these 36 deaths were equal to an annual death-rate of 2·4 per 1000. The deaths from measles, which had increased from 7 to 25 in the three preceding weeks, declined to 17 in the week under notice; the 5 fatal cases of diphtheria were 4 in excess of the number in the previous week. The deaths referred to diseases of the respiratory system, which had declined from 62 to 44 in the three previous weeks, rose to 54 in the week under notice. Thirteen deaths were attributed to different forms of violence, and 83 were recorded in public institutions. The causes of 10, or 3·6 per cent., of the deaths were not specified or not certified.

In Edinburgh 105 births and 95 deaths were registered in the week under notice. The deaths were 13 fewer than the number in the previous week, and were equal to an annual rate of 15·5 per 1000, against 15·1 and 17·6 in the two preceding weeks. The 95 deaths from all causes included 6 which were referred to the principal epidemic diseases, of which 4 resulted from diphtheria and 2 from measles; these 6 deaths were equal to an annual rate of 1·0 per 1000. The deaths referred to diseases of the respiratory system, which had averaged 18 in the four preceding weeks, declined to 12 in the week under notice. Three deaths were attributed to violence, and 44 were recorded in public institutions. The causes of 2, or 2·1 per cent., of the deaths were not certified.

The weekly returns issued by the Registrar-General of Scotland will, from the commencement of the current year, relate to the 18 largest Scotch towns, which at the last Census contained populations exceeding 30,000 persons. The aggregate population of these towns in the middle of the present year is estimated to be 2,182,400 persons. During the week ending Jan. 6th, 1037 births and 705 deaths were registered in these 18 towns; the deaths were equal to an annual rate of 16·9 per 1000, or 1·6 per 1000 above that recorded in the 94 English towns.

In the eight towns to which the Scotch return formerly related, the death-rate last week was equal to 17·4 per 1000, against 18·6 and 17·3 in the two preceding weeks. The annual death-rates in the several towns ranged from 3·4 in Partick, 11·6 in Kirkcaldy, and 13·2 in Govan, to 22·5 in Hamilton, 23·3 in Clydebank, and 24·7 in Greenock. The 705 deaths from all causes in the 18 towns included 83 which were referred to the principal epidemic diseases, and included 34 from measles, 13 from diphtheria, 13 from whooping-cough, 11 from scarlet fever, 8 from infantile diarrhœa, 2 from enteric fever, and 2 from typhus, but not one from small-pox. These 83 deaths were equal to an annual rate of 1·9 per 1000, or 1·0 per 1000 above that recorded in the 94 English towns from the same diseases. Of the 34 deaths from measles, 13 were registered in Glasgow and 9 in Aberdeen; 3 deaths from scarlet fever were recorded in Glasgow, 3 in Aberdeen, and 3 in Greenock; the 2 fatal cases of typhus occurred at Motherwell.

The deaths referred to diseases of the respiratory system in the 18 towns numbered 134, and 22 deaths were attributed to different forms of violence. The weekly return of the Registrar-General for Scotland no longer affords information as to the numbers of uncertified causes of death, or of deaths occurring in public institutions.

HEALTH OF IRISH TOWNS.

In the 22 town districts of Ireland, having an estimated population of 1,149,495 persons in the middle of the year 1911, 560 births and 396 deaths were registered during the week ending Dec. 30th, 1911. The annual rate of mortality in these towns, which had been 20·9 and 18·2 per 1000 in the two preceding weeks, further declined to 18·0 in the week under notice. During the 13 weeks of the fourth quarter of last year the mean annual rate of mortality in these towns averaged 18·4 per 1000; while the death-rate in the 77 large English towns during the same period did not exceed 14·7 per 1000. The annual death-rates in the week under notice in the several Irish towns were equal to 19·9 in Dublin (against 15·3 in London), 16·9 in Belfast, 21·1 in Cork, 14·1 in Londonderry, 20·4 in Limerick, and 7·6 in Waterford, while in the 16 smallest of these Irish towns the death-rate did not exceed 16·6 per 1000.

The 396 deaths from all causes in the 22 Irish towns were 5 fewer than the number in the previous week, and included 34 which were referred to the principal epidemic diseases, against 35 and 39 in the two preceding weeks; of these 34 deaths, 10 resulted from whooping-cough, 7 from diarrhœal diseases, 6 from scarlet fever, 5 from diphtheria, 4 from measles, and 2 from enteric fever, but not one from small-pox. These 34 deaths from the principal epidemic diseases were equal to an annual death-rate of 1·5 per 1000, and was 0·6 per 1000 above the mean rate from the same diseases in the 77 large English towns. The deaths attributed to whooping-cough, which had increased from 6 to 16 in the three preceding weeks, declined to 10 in the week under notice, and comprised 4 in Dublin, 3 in Belfast, and 3 in Lurgan. The deaths referred to diarrhœal diseases, which had been 11 and 4 in the two previous weeks, rose to 7 during the week, all of which were of infants under two years of age; 3 deaths were recorded in Dublin and 3 in Belfast. The fatal cases of scarlet fever which had been 3 and 4 in the two preceding weeks, rose to 6 in the week under notice, of which 5 were registered in Belfast and 1 in Dublin. The 5 deaths referred to diphtheria were 4 less than in the number in the previous week, and comprised 3 in Dublin and 2 in Belfast. Three of the 4 fatal cases of measles were recorded in Dublin, while the 2 deaths from enteric fever were registered in Dublin and Newry respectively.

The deaths referred to diseases of the respiratory system, which had been 105 and 83 in the two preceding weeks, rose to 85 in the week under notice. Of the 396 deaths from all causes in the 22 Irish towns 120, or 30 per cent., were recorded in public institutions, and 10 were attributed to different forms of violence. The causes of 22, or 5·6 per cent., of the total deaths during the week under notice were not certified either by a registered medical practitioner or by a coroner after inquest, while in the 77 English towns the proportion did not exceed 1·2 per cent.

In the 22 town districts of Ireland, having an estimated population of 1,157,014 persons in the middle of this year, 598 births and 413 deaths were registered during the week ending Jan. 6th. The annual rate of mortality in these towns, which had declined from 20·9 to 18·0 in the three preceding weeks, rose to 18·6 per 1000 in the week under notice. During the 13 weeks of the fourth quarter of last year the mean annual rate of mortality in these Irish towns averaged 18·4 per 1000, and was 3·7 per 1000 above the mean rate recorded in the 77 large English towns. The annual death-rates last week in the several Irish towns were equal to 23·3 in Dublin (against 15·5 in London), 17·2 in Belfast, 17·7 in Cork, 19·1 in Londonderry, 9·5 in Limerick, and 17·1 in Waterford, while in the 16 smallest of these Irish towns the death-rate did not exceed 13·3 per 1000.

The 413 deaths from all causes in the 22 Irish towns were 18 in excess of the number in the previous week, and included 29 which were referred to the principal epidemic diseases, against 39 and 34 in the two preceding weeks; of these 29 deaths 7 resulted from diphtheria, 6 from measles, 6 from diarrhœal diseases 4 from scarlet fever, 4 from whooping-cough, and 2 from enteric fever, but not one from small-pox. These 29 deaths from the principal epidemic diseases were equal to an annual rate of 1·3 per 1000; the death-rate from these diseases did not exceed 0·9 in the 94 English towns, while in the 18 Scotch towns it was equal to 1·9 per 1000. The 7 deaths attributed to diphtheria were equal to the average in the two preceding weeks, and comprised 4 in Dublin and 3 in Belfast. The deaths referred to measles, which had been 7, 6, and 4 in the three preceding weeks, rose last week to 6, all of which occurred in Dublin. Five of the 6 deaths from diarrhœal diseases, all of which related to infants under two years of age, were recorded in Dublin. The 4 fatal cases of scarlet fever, of which 3 were registered in Dublin, were equal to the average in the three preceding weeks. The deaths attributed to whooping-cough, which had been 16 and 10 in the two preceding weeks, declined to 4 last week, and included 2 in Belfast. The 2 fatal cases of enteric fever were recorded in Dublin.

The deaths referred to diseases of the respiratory system, which had been 83 and 85 in the two preceding weeks, further rose last week to 99. Of the 413 deaths from all causes in the 22 Irish towns 143, or 35 per cent., were recorded in public institutions, and 4 were attributed to different forms of violence. The causes of 15, or 3·6 per cent., of the total deaths during the week under notice were not certified either by a registered medical practitioner or by a coroner after inquest; in the 94 English towns the proportion of uncertified causes of death last week did not exceed 0·9 per cent.

THE SERVICES.

ROYAL NAVY MEDICAL SERVICE.

THE following appointments have been notified:—Fleet-Surgeons: R. Hickson to the *Africa*; C. S. Woodwright to the *Minotaur*, additional, for sick quarters, Yokohama; J. E. Coad to the *Leviathan*, and for general staff duties; E. H. Hodnet de Courtmacsherry to the *Renown*; D. J. P. McNabb to the *Hercules*, and for general staff duties; R. Hill to R. M. Infirmary, Deal; and E. B. Pickthorn to the *Cressy*. Staff-Surgeons: J. Fullarton to the *Cressy*; H. W. M. Rees to the *Hawke*, for voyage out, and to the *Flora*; and K. H. Jones to the *Enchantress*. Surgeon R. F. MacMahon to the *Excellent*.

ARMY MEDICAL SERVICE.

Surgeon-General Sir Francis W. Trevor, K.C.S.I., C.B., K.H.S., is placed on retired pay (dated Jan. 1st, 1912).

ROYAL ARMY MEDICAL CORPS.

The undermentioned Captains to be Majors: Charles S. Smith, Arthur F. Carlyon, William C. Croly (dated Dec. 4th, 1911); Patrick H. Henderson, William M. H. Spiller, Archibald D. Jameson, Bernard B. Burke, Walter B. Fry, and Percy C. Douglass (dated Dec. 21st, 1911).

Lieutenant John Gilmour is seconded for service under the Foreign Office (dated Dec. 8th, 1911).

Surgeon-General A. T. Sloggett, C.B., C.M.G., principal medical officer of the Sixth (Poona) Division, has taken up duty as Principal Medical Officer, His Majesty's Forces in India, in succession to Surgeon-General Sir F. W. Trevor, K.C.S.I., C.B., retired from Jan. 1st. Lieutenant-Colonel

N. C. Ferguson, C.M.G., in charge of the Military Hospital at York, has been selected for the higher rate of pay under Article 317 of the Royal Warrant. Lieutenant-Colonel H. C. Thurston, C.M.G., at present serving at Aldershot, has been selected for appointment as Medical Officer to the Royal Military College, in succession to Lieutenant-Colonel C. C. Reilly, whose tenure of the appointment has expired. Lieutenant-Colonel F. J. Morgan, commanding the Station Hospital at Barrackpore, has been granted six and a half months' leave of absence home from India. Lieutenant-Colonel S. Westcott, lately in charge of the Military Hospital at Chakrata, United Provinces, has arrived home, tour-expired. Lieutenant-Colonel E. G. Browne has been selected for appointment to hold charge of the Military Hospital at Jullundur. Lieutenant-Colonel W. A. Morris, commanding the Station Hospital at Cawnpore. has been detailed as Senior Medical Officer in charge of the transport s.s. *Plassy*, leaving Bombay for Southampton on Jan. 11th. Lieutenant-Colonel R. L. R. Macleod has arrived home for duty from Aden on completion of his tour of foreign service.

Major H. B Fawcus, from Bloemfontein, has been selected to succeed Major C. F. Wanhill as Assistant Professor of Hygiene at the Royal Army Medical College. Major J. Hennessy, commanding the Station Hospital at Poonamallee, has been detailed for duty on board the transport s.s. *Dongola*, which left Bombay for Southampton on Dec. 28th. Major G. B. Riddick, at present serving at Maymyo, Burma, has been permitted by H.E. the Commander-in-chief in India to extend his tour of service by one year. Major R. C. Elliott has taken over charge of the Military Hospital at Jhansi. Major L. Way, from Cosham, has been appointed for duty with the Northern Army in India, and will be posted on arrival to the Seventh (Meerut) Division. Major L. P. More and Major W. A. Woodside have embarked for a tour of service in India. Major A. J. MacDougall, recently employed as Specialist Sanitary Officer at Ceylon, has been ordered to join the Irish Command, and on arrival will be posted to the Belfast District for duty.

Captain D. Ahern has been transferred from Alexandria to the Military Hospital at Cairo for duty. Captain H. T. Stack, from Londonderry, has taken up duty at Belfast. Captain J. E. Powell, from Rhayader Camp, has joined at Alderney. Captain H. H. J. Fawcett, from the Royal Victoria Hospital at Netley, has been posted to the Military Hospital at Maidstone. Captain E. M. Glanvill has been transferred from the Military Hospital at York to Leeds. Captain O. Ievers has arrived home from South Africa for duty on the Home Establishment. Captain A. F. Weston has embarked for a tour of service at Jamaica. Captain M. B. H. Ritchie has been granted six months' leave of absence home from India. Captain C. Scaife has been appointed Specialist in the Prevention of Disease, Bombay Brigade, and placed in charge of the Brigade Research Laboratory at Colaba. Captain D. T. McCarthy has been transferred from the Eighth (Lucknow) Division to Burma for a tour of service. Captain W. C. Nimmo, from Chakrata, has taken up duty at the Station Hospital, Meerut. Captain C. T. Edmunds, from Cherat, has been detailed for a course of instruction in radiography at the X Ray Institute, Debra Dun, United Provinces. Captain G. F. Dawson, from Meerut, has been appointed to the Station Hospital at Chakrata. Captain D. de C. O'Grady has been transferred from Barian to Peshawar for duty at the Military Hospital. Captain D. M. Corbett, from Dalhousie, has taken up duty at Multan.

Lieutenant R. C. Priest, on arrival in India for a tour of service, has been posted to the Eighth (Lucknow) Division, instead of the Fifth (Mhow) Division as previously directed. Lieutenant R. C. G. M. Kinkead, at present serving at the Military Hospital, Queenstown, has been placed under orders by the War Office for service in South Africa, and will embark about the end of January. Lieutenant R. C. Paris, from the Royal Victoria Hospital at Netley, has embarked for duty in India.

INDIAN MEDICAL SERVICE.

Lieutenant-Colonel G. F. W. Ewens has been appointed Superintendent of the Punjab Lunatic Asylum at Lahore, on return from leave of absence. Lieutenant-Colonel W. Westropp White has received an extension of his leave of absence home from India from the Right Honourable the Secretary of State. Lieutenant-Colonel R. B. Roe, principal medical officer of the Abbotabad and Sialkot Brigades, has been selected for appointment as Principal Medical Officer of the Karachi Brigade. Lieutenant-Colonel P. C. Strickland has arrived home on leave of absence from India.

Major R. P. Wilson, officiating civil surgeon at Cuttack, has been granted privilege leave, combined with furlough, for 15 months. Major H. E. Berry has been appointed Specialist in Ophthalmology to the Fifth (Mhow) Division. Major J. W. Cornwall has arrived home on leave of absence from Madras Presidency.

Captain B. Higham has been selected to officiate as Deputy Sanitary Commissioner of the Central Registration District, Bombay. Captain O. A. Sprawson has been selected for appointment as Professor of Physiology at the Lucknow Medical College. Captain A. W. Overbeck Wright, officiating superintendent of the Central Prison at Agra, has been appointed to officiate as Superintendent of the Lunatic Asylum at Agra. Captain R. E. Lloyd, professor of biology at the Medical College, Calcutta, has been granted furlough out of India for two years. Captain R. B. S. Sewell, surgeon naturalist to the Marine Survey, has been appointed to officiate during Captain Lloyd's absence. Captain A. G. McKendrick has been placed on special duty under the Acting Sanitary Commissioner with the Government of India. Captain W. C. Long has been granted combined leave and furlough on medical certificate for one year. Captain R. McCarrison has arrived home on leave of absence from India. Captain J. H. Burgess has been appointed Specialist in Advanced Operative Surgery to the Ninth (Secunderabad) Division of the Southern Army. Captain R. T. Wells has taken up duty as Superintendent of the Dera Ghazi Khan Jail. The services of Captain E. J. C. McDonald, plague medical officer at Gurgaon, have been placed at the disposal of the Government of India, Department of Education. Captain W. J. Powell, officiating superintendent of the Central Jail at Jubbulpore, has been appointed to officiate as Civil Surgeon of Jubbulpore during the absence on leave of Major P. F. Chapman. H.E. the Governor of Bombay in Council has been pleased to appoint Captain J. Smalley to act as Second-class Surgeon, Ahmednagar. Captain J. W. Barrett has returned to India on the expiration of his leave of absence. Captain H. Halliday has taken up duty at Lyallpur as Civil Surgeon. Captain P. S. Mills, whose services have been temporarily placed at the disposal of the Punjab Government, has been appointed Plague Medical Officer at Delhi, vice Captain H. C. Keates, transferred to civil employment.

TERRITORIAL FORCE.

Royal Army Medical Corps.

2nd South Midland Mounted Brigade Field Ambulance, Royal Army Medical Corps:—The undermentioned officers to be Captains (dated Nov. 13th, 1911): Lieutenant Alfred W. Moore and Lieutenant Gurney W. Buxton.

Welsh Border Mounted Brigade Field Ambulance, Royal Army Medical Corps: Captain Alexander G. Hamilton to be Major (dated Jan. 6th, 1912). Captain James Herbert Dixon, from the list of officers of the Royal Army Medical Corps attached to Units other than Medical Units, to be Captain (dated Jan. 6th, 1912).

1st London (City of London) Field Ambulance, Royal Army Medical Corps: Arthur Donald Griffith to be Lieutenant (dated Nov. 22nd, 1911).

2nd North Midland Field Ambulance, Royal Army Medical Corps: Claude Marriott Cowper to be Lieutenant (dated Oct. 17th, 1911).

Attached to Units other than Medical Units.—The undermentioned officers to be Captains: Lieutenant Hugh Richardson (dated Jan. 1st, 1909), Lieutenant Percy Moxey (dated Oct. 1st, 1911), and Lieutenant Harry F. Wilkin (dated Nov. 19th, 1911). Captain Oliver Eaton resigns his commission (dated Jan. 6th, 1912).

For Attachment to Units other than Medical Units.—Devonshire Penrose Hawkes Gardiner, to be Lieutenant (dated Nov. 1st, 1911).

JOURNAL OF THE ROYAL ARMY MEDICAL CORPS.

In the opening number of the new volume of this journal Lieutenant-Colonel Sir William B. Leishman continues his Critical Review of Kala-azar and Tropical Sore. A joint paper by Major T. W. Gibbard, Major L. W. Harrison, and Lieutenant A. S. Cane deals with Further Investigations on the Use of Salvarsan in Syphilis. Its authors have had

great success with the technique which they have adopted, but they add a note of warning that "the fact that there is nothing in the technique which is beyond the capacity of anyone with ordinary skill and intelligence does not make salvarsan a remedy which can be administered carelessly with impunity." Captain G. J. Keane has some Notes on the Treatment of Syphilis in Uganda, which will be read with interest. The author points out that the natives will be wiped out by syphilis unless energetic measures are taken to enforce more strongly the treatment of the disease. Major M. H. Babington's article on An Outbreak of Paratyphoid B. Fever in Malta is also worthy of attention. In a note which occupies only two pages Colonel R. H. Firth makes a suggestion which, though perhaps not absolutely novel, comes with striking force from a scientific journal. After referring to the work of Loeb on parthenogenesis and its extension by other investigators, Colonel Firth points out that Bataillon of Dijon has succeeded in mechanically fertilising the ripe eggs of the common frog with the ultimate production of tadpoles as a result. Thus the segmentation brought about by altered environment of the ova of invertebrate animals in which gamogenesis is normal, has been followed by the fertilisation of the ova of a vertebrate animal without the physical contact of the two sexes. This, Colonel Firth suggests with all reverence, may throw light on the story of the birth of Christ. The time was not so very long ago when the Church looked upon science as her enemy, but it is more and more being recognised that the Church and Science may be expounders of two aspects of one truth. "This generation," says the author, "may not live to see the removal of all the difficulties which stand in the way of a scientific explanation of many things which are still mysteries, yet, in the light of what little glimmer we possess, it is desirable that hasty criticism of unintelligible things should be avoided."

Correspondence.

"Audi alteram partem."

THE MEDICAL PROFESSION AND THE NATIONAL INSURANCE ACT.

To the Editor of THE LANCET.

SIR,—Sir Alfred Pearce Gould's judicious letter in your columns cannot fail to have a good effect upon our sadly distraught profession. The great need now is to search out our points of agreement and work steadily together for their achievement. No sense of false pride or petty ambition must stand in the way of making use of every individual or institution that may be useful in securing our common aim. In our search for points of agreement, points of disagreement, some old and well known, others new and forced to the front by powers outside ourselves, will certainly be conspicuous. These latter can only be met either by a loyal submission of the minority to the views of the majority or by considered compromise.

Sir Alfred Pearce Gould and I, I fear, will never agree as to the merits and demerits of "contract practice." I cannot bring myself to believe that my professional colleagues are so different from mankind in general that it is impossible to obtain from them the best work unless for each item of added service they receive additional remuneration. This principle of payment is absent from the remuneration given to the navy, the army, the church, to the majority of teachers, and even to Cabinet Ministers. Those who believe that this principle must be an essential feature in professional remuneration in order to secure efficient service, are in my opinion misreading human character as badly as are those who assert that surgeons who receive large fees for each service rendered are incapable of making their pecuniary interest subservient to their patient's welfare.

I believe that medical men when properly paid, by whatever system, will give the best service of which they are capable, even as I rejoice to believe the majority of medical men do now, however inadequate their pay may be. Despite our fundamental differences, I am sure that if it were necessary in the interests of the profession Sir Alfred Pearce Gould or I, finding himself in the minority on this question, would loyally support the wishes of the majority. Fortunately this is not necessary. As Sir Alfred Pearce Gould points out in his letter, "the Act is wide and vague." It will therefore be possible for us to compromise and to support the fourth cardinal point as follows: "*The method of remuneration of medical practitioners adopted by each Local Health Committee to be according to the preference of the majority of the profession of the district of that committee.*" In some districts we may have a "capitation grant," in others a "fee for attendance," and in yet others, perhaps, we may have a combination of these two methods—a smaller capitation retaining fee combined with a fee for each attendance. It even seems possible that in some districts the medical benefit for all insured persons may take the form of a direct contribution to the cost of medical attendance.

To secure that these diverse systems shall be set up on a proper basis so as to provide adequate remuneration and other conditions of service satisfactory to the profession, medical men must present a united front. As Sir Alfred Pearce Gould says, the profession must look to the British Medical Association to take the chief part in this work. Valuable help may be given by the Royal Colleges and other institutions. The profession must, however, never forget that the only body in the deliberations of which representatives of every class of practitioner, medical officers of the Royal Household and of Poor-law unions, censors of the Royal College of Physicians and colliery doctors, surgeons who earn 100 guineas in an hour and others who earn scarcely so much in a year, can meet on equal terms and support such of their special privileges and interests as do not clash with the common good, is the British Medical Association. I am, Sir, yours faithfully,

Harley-street, W., Jan. 8th, 1912. LAURISTON E. SHAW.

To the Editor of THE LANCET.

SIR,—We must all be grateful to you for your endeavours to unite the profession, and as one who feels keenly the need of some strong lead in the direction of practical unity, I venture to ask you to permit me to offer a few suggestions.

It seems to me that the profession is absolutely united in its desires, but hopelessly disunited as to the means by which these should be attained. I take it that we all feel on the one hand that an income-limit of not more than £2 a week is the irreducible minimum under which the profession could work the Act, and that the financial estimates under which the Act has been prepared are quite inadequate to meet the needs of the case, and we are determined that unless these difficulties can be got over no one should undertake to give medical treatment under the Act.

When, however, we come to consider how these difficulties may be met there seem to be three policies advocated by different sections of the profession: (*a*) One section appear to be of opinion that it is impossible under the Act to get these demands adequately conceded, and therefore that the only thing to be done is to refuse to have anything to do with the Act, whether in the way of forming Medical Committees or accepting posts on Insurance Committees, and of course of forming a panel. (*b*) Another section believe that it might be possible to obtain the concessions desired from the Insurance Commissioners, and consider that unless the Insurance Commissioners will agree upon conditions applicable to the whole Kingdom, which would therefore all be on the same scale, no one should undertake to give medical treatment under the Act. (*c*) The third section appear to think that it may be necessary to have somewhat modified regulations for different districts, and that it might even be better that these should be arranged locally, provided that these arrangements come under the irreducible minimum already referred to, but that no one should agree to give medical treatment under the Act unless these arrangements were satisfactorily conceded in every part of the country. I suppose that the third alternative would be regarded as practically the policy of the existing Council of the British Medical Association.

The first alternative appears to be the policy of the *Practitioner* and apparently of the new Manchester association. Dr. F. J. Smith's committee do not seem to have committed themselves to any definite policy, and they probably consist mainly of supporters of (*a*) and (*b*), with a small section of supporters of (*c*). The object of the supporters of (*a*) appears to be to endeavour to wreck the

Act, but it is a difficult and perhaps a dangerous thing to run counter to an Act of Parliament, and to endeavour to do so usually brings loss and discredit upon those who make the attempt. Between (*b*) and (*c*) it would seem to me to be difficult to make a decision apart from the best expert advice, and it appears to be between these two policies that the British Medical Association will have to decide, and if a wise decision is to be made it will, in my opinion, depend not upon clamorous meetings or violent newspaper letters, but upon the clear hard thinking of the men of business in our profession. Unfortunately the use of the terms such as "The Great Betrayal" or the accusations of political motives which have been freely bandied about have done much to render such careful thinking difficult, if not impossible.

My suggestion certainly would be that the matter should be now left to be decided by the different divisions of the British Medical Association and by its Representative Meeting. It is said that the newly formed bodies are intended to support the British Medical Association, but divided counsels are always dangerous, and I hope that we shall all agree to adopt the only constitutional action, at least to those of us who are members, of working through the existing constitution of the British Medical Association, and that whatever is decided by the majority after careful consideration may be supported loyally by us all.

I have ventured in a letter to the *Times* of Dec. 26th to recommend that three of the leaders of the profession—the President of the General Medical Council, the President of the Royal College of Physicians, and the President of the Royal College of Surgeons—should be asked to arbitrate between the conflicting sections of the profession. My meaning was not that they should attempt to settle for us what policy we should adopt, but what method we should adopt for arriving at our policy. I believe that if the different organisations concerned would be willing to be guided by some such impartial authority a great step towards peace and unity would be accomplished.

Apologising for trespassing at so great length upon your space, I am, Sir, yours faithfully,

CHARLES F. HARFORD.

Livingstone College, Leyton, E., Jan. 8th, 1912.

To the Editor of THE LANCET.

SIR,—The exhaustive article in your issue of to-day, together with the instructive letter of Sir Alfred Pearce Gould, should be of the greatest value to the profession, and the question that he has put at the end of his letter—namely, "Shall the scheme of 'medical benefit' be formulated by the Insurance Commissioners or Local Health Committees, or shall it be formulated by the profession and pressed upon these bodies?" can only be answered in one way, that is, as he urges—by the profession.

The profession, however, has not before it, either in the Act or from any official or other source, any intimation as to the services which will be required from medical men accepting service under the Act, and until their duties and responsibilities are distinctly stated I would urge that the amount or kind of remuneration cannot with any advantage be even considered. I feel sure that the profession would be glad to assist in making the Act a success, but it must be assured that the interests of the nation will be protected, and that the medical service shall be far above any hostile criticism.

It must be remembered that for the first time in the United Kingdom the State has now accepted the responsibility of giving "medical benefit"—not to paupers, but to a mass of people who will have compulsorily to pay for its medical service, and who will naturally insist on having the best. I feel quite sure that the profession will wish to supply an up-to-date and splendid medical service to the people under the ægis of the State—a service which must advance with the times and be always efficient on the most scientific lines, but modern medicine and surgery in their higher forms require heavy expenditure in the necessary appointments of a well-ordered clinic. With my intimate knowledge of every class of practice I am obliged to point out that there are many surgeries in crowded neighbourhoods where cheap or club practice is carried on which are not adequately fitted for the realisation of the above ideal. This statement may be unpalatable, but the present condition of things must be faced. I feel very strongly that with "free choice of a doctor," although the assured may exercise the "free choice," the State will still be responsible and will have to see that the surgeries have every possible convenience and appliance for the proper and efficient practice of modern medicine and surgery.

Who is to pay for these properly fitted surgeries, with instruments, sterilising baths, electrical appliances, hot and cold water, and antiseptic dressings of all kinds? Will the Insurance Commissioners make grants to doctors on the panel, or will the doctors who accept service be required to go to large expenditure in providing for the requirements of the service? It must be perfectly understood by the profession that over 15,000,000 people will have to be catered for, that there will be no out-patient departments of hospitals giving free medical attendance, and with the "free choice of a doctor" the popular man for the time being will be overworked, and after having provided proper accommodation for a large number of patients may the next year, the popular favour having gone to others, find himself involved in heavy loss; also every medical man on the panel will have no security of tenure, but will hold his office at the will of an Insurance Commission, not an unbiased, independent body, but a board composed of Friendly Society officials, with but one medical man on it, who could not possibly have sufficient weight to influence the other members, however well-disposed to the profession he might be.

The surgeries must be fitted for the proper treatment of casualties and urgent cases, but under the Act medicines are to be provided by pharmaceutical chemists. Are they to provide waiting-rooms? Are their shops to be near the surgeries? Will they provide expensive medicines on the unfettered prescriptions of medical men on any capitation system? If not, are medical men on the panel to provide medicines on terms which others have refused?

Are the medical men accepting service to undertake the treatment of fractures and perform all operations that may be necessary, or are they only to treat ordinary cases, sending serious or special cases to the nearest hospital? If the latter, what arrangements are to be made with the hospitals? The out-patient departments can be turned into clinics for the treatment of special cases and the beds can be used for insured persons; but insured persons who have paid the State for "medical benefit" will not be satisfied with the hospital conditions now provided for persons seeking gratuitous aid at the expense of the benevolent. They will demand, and rightly demand, the attention due to those who compulsorily, and in many cases against their will, have been obliged to pay for "medical" benefit to be provided by the State.

A question therefore arises, Will the voluntary hospitals be taken over by the State and the staff adequately paid, or if not are medical men on the panel to attend serious cases in the homes of the insured, homes in some cases of the most dirty and squalid description? When all these questions have been considered and decided, then, and not until then, the profession will be able to formulate a scheme of remuneration through a central body having the confidence of all its members. I trust that no attempt will be made to enter upon local bargaining with Insurance Committees or Commissioners dominated entirely by Friendly Societies.

I venture, in supporting Sir Alfred Pearce Gould's opinion, to ask him to gather together a strong committee, with a view to the drawing up of a statement showing the minimum that the State could possibly offer as "medical benefit" to self-respecting people, many of them able and willing to pay for medical treatment, but who will have compulsorily in the future to pay the State for medical service. With such a statement before them showing the duties, responsibilities, and requirements of the service, the question of remuneration would be easy of adjustment, equitably and to the advantage of both the State and the profession.

I am, Sir, yours faithfully,

Hampstead, N.W., Jan. 6th, 1912. ALBERT BENTHALL.

To the Editor of THE LANCET.

SIR,—The recent correspondence in your contemporary the *Times* by Mr. Boyton, Mr. Smith Whitaker, Sir Henry Craik, and Sir Philip Magnus has left an uneasy impression on my mind that Mr. Smith Whitaker is not receiving fair treatment. He was the paid servant of the British Medical Association, and as such conducted a missionary tour to its divisions before the introduction of the Bill, and also acted as a negotiator during its passage through the Houses of Parliament. He subsequently received a substantial recognition of his services from the Government. Under these circumstances appearances favour on the one hand the supposition that in view

of the fact that there were numerous official and unofficial interviews taking place between him and the Chancellor extending over the periods both before and after the introduction of the Bill, he was the tool of the Chancellor and his political supporters, and on the other hand, the supposition that Government supporters belonging to the Association were instructing him as to his course of procedure.

It is incredible to me that the governing authority of the Association did not give him written instructions as to the course which he was to pursue, both during his missionary tour and during the negotiations which he conducted with the Chancellor. It, therefore, appears to me highly desirable, in justice to Mr. Smith Whitaker, that such instructions should be published, and it is also desirable that the country should know how far the Government has conducted the negotiations with the British Medical Association with clean hands.

I am, Sir, yours faithfully,

Hatfield, Jan. 4th, 1912. LOVELL DRAGE.

To the Editor of THE LANCET.

SIR,—Much as we dislike it, the National Insurance Act has come to stay, and we must make the best of it. Apart from the medical benefits it has many commendable points which in time will be appreciated by the public. On the other hand, the clauses relating to medical benefits are most unsatisfactory, but they appear to be elastic.

The "six cardinal points" of the British Medical Association have not been accepted by Parliament, and I feel sure that it would now be a waste of time and energy to agitate for their incorporation in the Act. It may be that it is well for the profession and the public that the "six cardinal points" or the most essential of them were rejected, as their adoption would undoubtedly have perpetuated the objectionable *per capita* system of payment.

We are now free to demand our own terms, and I sincerely hope that we shall be unanimous in demanding payment for actual services rendered. I can see nothing in the Act to prevent the Insurance Commissioners from giving this method a trial, and if we give them plainly to understand that we are determined not to work under the Act unless we are paid according to an agreed minimum scale for actual work done, it is possible that this essential will be conceded.

In July last the Imperial Medical Reform Union sent out 20,000 referendum forms to practitioners in England and Wales inviting them to state whether in favour of capitation payment or for services rendered, and of the replies received more than 95 per cent. were in favour of the latter method of remuneration. The adoption of this method is, in the opinion of the Council of the Union, the only way to preserve the independence of the profession.—I am, Sir, yours faithfully,

GEORGE BROWN,
General Secretary of the Imperial Medical Reform Union.

Basinghall-street, E.C., Jan. 9th, 1912.

To the Editor of THE LANCET.

SIR,—May I ask space in your valuable paper to call the attention of my fellow medical practitioners to the extreme danger to themselves and to the profession at large in rashly signing any pledge or undertaking not to work under the National Insurance Act. It is quite patent that a great deal of the materials published in the lay press is purely of a general political anti-governmental colour, aimed at increasing subscribers to certain papers, and serving up pabulum for lay readers at the expense of the medical profession, whose real interests are sacrificed and the profession put out of court and rendered powerless by their present attitude of "*ruat cœlum.*" I do not feel myself at liberty to say more, and remain,

Yours faithfully,

F. W. FORBES-ROSS, M.D. Edin., F.R.C.S. Eng.

Harley-street, W., Jan. 6th, 1912.

To the Editor of THE LANCET.

SIR,—What is the use of all this outcry against Mr. Lloyd George's offer to buy our services for his big national club at the rate of 4*s.* 6*d.* a head? How can we reasonably refuse to serve under his scheme when hundreds, perhaps thousands, of us are now working for clubs at that rate and less, and hundreds more are hungering for the jobs? How can we blame the Chancellor for taking us at our own valuation and offering to buy us at market price, the price fixed by our own competitive folly in the open, unorganised, medical labour market? No one will believe our demands to be just as earnest while our acts thus belie our words. To regularise our position every club should be notified that on and after July 1st our charge per member would be 8*s.* 6*d.* (or thereabout), otherwise all contracts to cease.

I am, Sir, yours faithfully,

City-road, E.C., Jan. 8th, 1912. H. G. DIXON.

To the Editor of THE LANCET.

SIR,—In connexion with recent correspondence in your columns, my attention has been called to By-law 39, Sect. 4, of the British Medical Association regulations, which enacts as follows: "In voting upon any matter upon which a constituency has passed a resolution within the three months immediately preceding such meeting the Representative or Representatives of that constituency shall be under obligation to vote in accordance with such resolution." It is obviously important that in future the representatives have a clear understanding as to their duties in the matter of voting.

I am, Sir, yours faithfully,

London, S.W., Jan. 8th, 1912. EDWIN SMITH.

To the Editor of THE LANCET.

SIR,—Will you allow me space in your valuable journal for a brief reference to Dr. Edwin Smith's letter in your issue of Dec. 30th. I was present as an onlooker at the Representative Meeting to which he refers (Nov. 23rd), and myself heard Dr. Maclean instruct the delegates that in their voting "they were to vote in accordance with their conscientious opinion on the subjects that arose for consideration." I was amazed when I heard him say this, for obviously the delegates were there as representatives of the divisions only to the extent of expressing the views of the divisions, which had been considered at the meetings held previously throughout the country, certain definite points to vote on, for or against, having been submitted to them previously for their consideration. If, then, the chairman (Dr. Maclean) instructed the delegates to vote in the manner referred to, and assuming they did so, the meeting, I submit, ceased to be representative of the views of the profession. We owe Dr. Smith a debt of gratitude for his efforts to ventilate the matter. Again, as an onlooker, I could not help feeling that an attempt was being made, as Dr. Smith says, to fritter away the time of the meeting in futile discussions. I entirely agree with him that the consideration of the *number* of medical men (i.e., 3, 5, or 8 against 80) on the committees is not worth a thought, as in either case they would be powerless.

Dr. Maclean, according to his own statement, had received the offer of Mr. Lloyd George of the post of Commissioner for the secretary of the Association, and in my opinion there would have been no breach of confidence if he had openly explained this to the Representatives instead of talking of "smoke-room rumours," &c. Had he done this it is certain the Representatives would have voted very differently from the manner in which they did.

I was present at the Battersea town-hall when Dr. Lauriston Shaw addressed the Wandsworth division, and was astonished to hear him say that the doctors could have "8*s.* 6*d.* or 10*s.* per annum or 2*s.* 6*d.* per visit if they preferred it." There may be no legal barrier to this, but there is every other conceivable barrier, and when he made this statement he should have known this well. It looks as though this statement was made only to prevent those present from supporting the resolution which Dr. Edwin Smith had moved calling on the Council to resign, and I at any rate trust that no steps will be left untaken that will lead to the compulsory resignation of the Council.

I am, Sir, yours faithfully,

REGINALD THORPE, M.R.C.S. Eng., L.R.C.P. Lond.

Elmbourne-road, Tooting Bec Common, S.W., Jan. 6th, 1912.

*** We hope to publish later some of the many letters on this subject still in our hands.—ED. L.

THE MORBID DIATHESES.

To the Editor of THE LANCET.

SIR,—I am glad to find my old teacher Sir Dyce Duckworth raising a mild protest in THE LANCET of Jan. 6th (p. 54) against the too exclusive attention bestowed in the Bradshaw lecture[1] upon the parasite as against the host, or in his words, upon the seed as against the soil.

In my time, even long after "those dark days" of Mr.

[1] THE LANCET, Dec. 23rd, 1911, p. 1756.

Clement Lucas, Sir Dyce Duckworth—possibly more than any other teacher at St. Bartholomew's—urged that successful medical practice consisted in "treating the patient rather than the disease," a dogmatic maxim of profound truth which not only encouraged his students to study their "cases," but which also enables those who practise especially in the department of mental medicine to treat successfully, and happily in many instances to ward off, the most disabling scourge which can afflict the human race.

In his "thundered out" destructive criticism of diathesis, the Bradshaw lecturer has been carried by the interest of his subject further than he possibly intended, for—and this is why I write—as the orator of the Royal College of Surgeons he lends the influence of his powerful authority and position (to quote his words) "to destroy the reproductive function of the generative organs without ..... the knowledge of the individual" in cases of lunacy! He varies his theme "on some points in heredity" by an excursion into eugenics, and points out that the present moment would seem to be a favourable time for medical men to press upon the Government for some drastic measure for the protection of the State against the gradual increase of lunacy. Apart from the intrusion of medical men into politics—and not with the most happy experience if recent events are to yield a precedent—it may be well to note here that an inquiry made by a medical officer (Dr. G. Clarke) in one of the London asylums elicited the information that if the parents of those who were admitted insane had themselves been treated in the manner recommended by Mr. Lucas only about 1 per cent. of the offspring referred to would have been saved the scourge of insanity—i.e., insanity had occurred in the parents in nearly 99 per cent. after the birth of the certified patients. If every defective were deprived of those organs which are stated to belong to the next generation, then on the morrow there would be defectives again. Degeneration and defect are not the consequence of defective seed alone. By common consent they are equally the product of the environment or soil, and they are attendant upon evolution towards the perfect. In this progress towards perfection defectives will never be wanting. Defectives came not originally from other defectives, but from normal types. It is by no means certain that the offspring of two defectives even will be defective. The following letter from an old patient illustrates my point, although by itself I acknowledge that it carries no great weight:—"You will remember some years ago my giving birth to a child at the asylum. ..... I am pleased to tell you he is (up to the present) a very good boy. He has been awarded four medals and several prizes and is in the highest standard in the school."

Hitherto no pathogenic organism has been connected with insanity, and it may be stated to possess no more clearly defined pathology than in "those dark days" when insanity was recognised to have a definite "diathesis," and which, in the opinion of many, is still to-day a real condition—i.e., if such may be interpreted to imply a *tendency*, under certain conditions, for the tissues inherited from the parents to develop disease on certain definite lines; in other words, a defective constitution (soil) which is inherited and which is so constructed as to permit of readily disordered metabolism under the influence of some specific or non-specific organism (seed).

The views of a great surgeon upon biological problems cannot fail to be of interest to those who are attempting to unravel the facts of experience, even if these are only on the subjective side. Mr. Lucas supports his destructive criticism in regard to leprosy from Holy Writ and refers to the discovered "seed." May I also quote from Holy Writ and draw the attention of the lecturer to the parable of the sower which gives the vicissitudes of the seed resulting from environment? That which fell by the wayside served only as food for birds, that on stony places became scorched and sunburnt, and that which fell among degenerate thorns was choked out! None of the effects were in the least attributable to defective seed. It is essential for good development to have good surroundings, and good environment is as essential as good seed. It is clear, as Sir Dyce Duckworth has pointed out, that the individual organisation (soil), or in the case of lunacy the environment, has intimate proclivities which it is the fashion to-day to ignore.

I am, Sir, yours faithfully,

Claybury, Jan. 9th, 1912. ROBERT JONES, M.D. Lond.

MINERS' PHTHISIS IN THE TRANSVAAL.

To the Editor of THE LANCET.

SIR,—From recent cables in the Johannesburg newspapers it is gathered that in your issue either of Dec. 1st or 8th, 1911, appears a somewhat sensational letter from a medical practitioner in this city in respect to miners' phthisis in the Witwatersrand Mines. This letter has also since been published here, and, with your permission, it is desired to refer to its last paragraph. In this paragraph are quoted certain statements by a local engineer and tutor, who is known to feel aggrieved that no member of the Commission (before which, of course, he had every opportunity of adducing any evidence he desired) will discuss its statistical and other findings publicly with him, or descend to any exchange of personalities. While this policy will be adhered to it is thought right that the history of the Mining Regulations Commission should for general information be briefly set out; for, though well known in Johannesburg, it is naturally little known elsewhere.

This Commission was appointed by his Excellency Lord Selborne on May 11th, 1907, and consisted of five members (Messrs. Krause, M.L.A. (chairman), Nicholson, Porter, Price, and Heymann). Its immensely wide reference was to inquire into and report upon the following matters:—

1. The working of the Mines, Works, and Machinery Regulations, and to make recommendations for any amendments thereto necessary for the better protection of the health and safety of persons working in mines, with special reference to the following subjects: (*a*) prevention of accidents; (*b*) ventilation; (*c*) underground sanitation; (*d*) change-houses.
2. The present system of measuring up work underground, and to make recommendations as to the necessity or otherwise for legislation on this subject.
3. The question of extending the operations of the Mining Certificates Ordinance, No. 50 of 1903, to engine-drivers driving stationary and traction engines, not being man-hauling engines.

In order to clear the ground it was decided to deal first with the second and third of the terms of reference as being matters of limited scope compared with those comprised under Term 1.

On Sept. 21st, 1907, an interim report upon these subjects was presented, which report is printed as Appendix "B" to the Final Report. The Commission then proceeded to take evidence on the very wide ground covered by Reference No. 1 and virtually completed this work by June, 1908. About this time, however, commenced the curious sequence of misfortunes with which the *personnel* of the Commission was pursued. In April, 1908, Mr. Nicholson resigned through ill-health and died shortly afterwards. In June, 1908, Mr. Price resigned and left the Transvaal, and in November, 1908, Dr. Porter went on sick leave until May, 1909. In September, 1909, Mr. Heymann met with a serious motor accident, and in October, 1909, developed dangerous illness which confined him to bed for eight months. The progress of the report was, therefore, considerably delayed, and the great labour of its preparation fell eventually mainly on the shoulders of the two remaining Commissioners, whose time was, even in the ordinary way, sufficiently occupied by their professional and official duties. They were, therefore, unable to report till March, 1910.

It must not, however, be thought (as is tacitly implied in the letter under reference) that nothing was done between June, 1908, when the taking of evidence finished, and August, 1910, when the report was published. For in November, 1908 (*vide* p. 40 of Report), the Commission made the strongest official interim representation to the Honourable the Minister for Mines on certain matters, and notably on the outstanding importance, from the point of view of dealing with miners' phthisis, of preventing and allaying dust in mines. As the result of the Commission's recommendations in November, 1908, the following additions to the Mining Regulations were gazetted on Dec. 24th, 1908:—

5. Every place where development work is carried on and where the natural strata are not wet, and every dry and dusty stope shall be adequately supplied at all times with suitable clean water. Such supply shall be continuous, and shall be sufficient for effectively damping the broken ground and for allaying the dust caused by drilling operations.
6. Blasting shall be so arranged that men working in other places shall be exposed as little as practicable to dust and smoke.
7. All plant, material, and other things necessary to enable the above rules to be carried out shall be provided and maintained in working order.

146 (II.). The ganger or miner in charge of workmen shall be responsible that the following provisions be observed: (1) No person shall in the drilling of holes use any percussion machine-drill unless a

water-jet or spray or other means equally efficient is provided and used so as to prevent the escape into the air of dust caused by the drilling. (2) No person shall in any part of a mine remove any broken rock or ground if such rock or ground is in a dusty condition until it has been effectively damped so as to prevent the escape of dust into the air during removal. (3) No person shall, after firing has taken place, whether by electricity or in any other manner, enter the place in which such firing has occurred until the fumes caused by the explosion shall have been sufficiently dissipated, unless such person is wearing an effective respirator or other apparatus to prevent the inhaling of fumes or dust.

We note that the statistical conclusions of the Commission have been characterised in the letter under notice as entirely below the mark, and based on wholly insufficient data and inquiry.

Now, the figures from which these conclusions were drawn covered the triennium 1905–07, and were furnished by Dr. Louis G. Irvine and Dr. D. Macaulay, for whom they had been excerpted with great care by Mr. Dawson Squibb, of the Transvaal Government Health Department, from the returns of the Mines Department and of the registrars of deaths. In the opinion of the Commissioners these figures were at that time (1908) sufficiently recent, and it was not reasonably practicable, under the then existing circumstances, to obtain more reliable data. Then, in order to determine the true significance of these figures, which were somewhat difficult to deal with, and are discussed at pp. 33–37 of the report, the Commission secured the coöperation of Mr. G. D. Maynard, whose expert knowledge of modern statistical methods is well known. The broad conclusions arrived at were as follows:—

1. That amongst "white mining males of 20 and over" during the triennium 1905-06-07 "phthisis" (including miners' phthisis) accounted for 43·1 per cent. of all deaths, "other respiratory diseases" for a further 17·9 per cent., making a total of 61 per cent. from "all lung diseases," the comparative figures for "non-mining males" at the same age being 10·2, 15·8, and 26.

2. That the death-rate from "phthisis" (including miners' phthisis) at ages of 20 and over was more than six times greater amongst "white mining males" than amongst white "non-mining males."

3. That for the three years 1905-06-07 the death-rates from "phthisis" (including miners' phthisis) amongst "white mining males" at ages of 20 and over were respectively 6·0, 5·3, and 6·4 per 1000. Statistical theory shows that variations as great as these may be expected apart from any real change in the incidence of the disease. It is therefore impossible to state from the evidence before us that any alteration in the phthisis death-rate took place during the years in question.

4. That the death-rate from "other respiratory diseases" amongst "white mining males" at ages of 20 and over was 70 per cent. greater than that amongst similar white "non-mining males"—viz., 1·7 to 1.

5. That when "phthisis" and "other respiratory diseases" are excluded there appears to be an appreciably lower mortality from "all other diseases" amongst white "mining males of 20 and over" than amongst white "non-mining males of 20 and over"; this may in part be due to the fact that the white miners' high death-rate from respiratory diseases tends in a limited degree to decrease the numbers at risk to other complaints, and to the further fact that when a person with chronic respiratory disease succumbs to an acute intercurrent non-respiratory complaint—e.g., enteritis—the older standing respiratory disease will usually appear in statistical returns as the cause of death.

6. That the "death-rate from all diseases" amongst white "mining males of 20 and over" is greatly in excess of that amongst white "non-mining males of 20 and over" when the necessary correction for age-constitution of white "mining males" is made; this excess is about 60 per cent.

Now, while these conclusions were possibly within the mark—a restraint often lamentably lacking in irresponsible criticism—they are strictly those justified by the figures before the Commission. With regard to alleged insufficiency of inquiry, it should be remembered that the Commission with its immensely wide reference, had neither the *personnel* nor the legal power to undertake the careful individual physical examination of many hundreds of miners, which the seriousness of the conditions as revealed by the Commission's report has since brought about. But before this important clinical work could even be attempted, a special Act of the Union Parliament was necessary in order to compel miners to submit to such examination, and seven medical men have since been engaged several hours a day for many months in carrying it out. Their findings will, we understand, be available at an early date.

As regards the general results of the Mining Regulations Commission's work, it is particularly gratifying to us to be able to state that practically all of its recommendations, including those regarding dust-prevention, mine-ventilation and air-standards, scavenging, water-supply, native diet, housing, first-aid and ambulance, were promulgated almost *verbatim* as regulations with the force of law, in *The Union Gazette Extraordinary* of Nov. 21st, 1911; and if these regulations are enforced we believe that they will place the hygiene of mining in South Africa on a higher plane than that of any other mining community of which we are aware.

We append copy of some of the regulations in question, and have the honour to be, Sir,

Your obedient servants,

F. E. T. KRAUSE, LL.D.
CHARLES PORTER, M.D.,
Medical Officer of Health of Johannesburg.
A. HEYMANN, M.A.,
Consulting Analytical Chemist and Metallurgist.

Johannesburg, Dec. 18th, 1911.

SOUTH AFRICAN UNION GAZETTE EXTRAORDINARY, 21ST NOVEMBER, 1911.

Regulations made under Section Four of the Mines and Works Act, 1911 (Act No. 12 of 1911).

CHAPTER I.—*Definition "Ventilating District."*—Ventilating district shall mean such part of a mine as has an independent intake commencing from a main intake air-course and an independent return air-way terminating at a main and return air-course.

CHAPTER II. *No. 7 (1).—Surface Protection.*—Water containing poisonous or injurious matter in suspension or solution must be effectually fenced off to prevent inadvertent access to it, and notice boards shall be put up in suitable places to warn persons from making use of such water. 2. In no case may water containing any injurious matter in suspension or solution be permitted to escape without having been previously rendered innocuous.

CHAPTER III.—*Underground protection.*—12. Where a place contains, or is likely to contain, a dangerous accumulation of water or noxious gases, any working approaching that place shall have boreholes kept in advance, and such additional precautionary measures shall be taken as may be deemed necessary to obviate the danger of a sudden breaking through of such water or gases, and such working place must not exceed six feet in width. A certificated surveyor shall exercise supervision at every such working place and shall be responsible for the correct direction of such working, and for the breaking through of such water or gases without accident. In the case of a mine for which there is no certificated mine surveyor, the manager shall have all the powers and responsibilities and perform all the duties conferred or imposed on a certificated surveyor in this regulation.

CHAPTER VI.—*Ventilation.*—56. (1) The vicinity of the collars of downcast shafts shall be kept clear of cinder heaps, and so far as practicable, of smoke. (2) The ventilating current from the downcast shall be suitably split to provide sufficient air to all working places. (3) In all portions of a mine or workings where the natural ventilating current is insufficient, suitable mechanical appliances for ventilation shall be provided and operated.

CHAPTER IX.—*Duties of Gangers, Blasting, &c.*—101. (1) No person shall in the drilling of holes use or cause or permit to be used any percussion machine drill unless a water jet or spray or other means equally efficient is provided and used so as to prevent the escape into the air of dust caused by the drilling, and unless the floor and sides of the working face to a distance of at least ten feet from the face be kept sufficiently damp to prevent dust being raised by the escape of exhaust air from the rock-drill. (2) No person shall in any part of a mine remove any broken rock or ground or cause or allow the same to be removed if such rock or ground is in a dusty condition unless and until it has been effectively damped and is kept damp so as to prevent the escape of dust into the air during removal. (3) Any mine in which in the opinion of the Inspector of Mines the dust produced by drilling is not likely to cause miners' phthisis shall be exempted from the provisions of sub-sections (1) and (2) of this Regulation.

CHAPTER XIV.—*Responsibility in connexion with Mines and Works, &c.*—158. In addition to his other duties and responsibilities under these regulations the manager shall:—(1) Provide or cause to be provided on the surface, and in the case of a mine in the underground workings, sufficient and suitable sanitary conveniences in accordance with the following rules: (*a*) Where the number of persons employed does not exceed one hundred there shall be one sanitary convenience for every twenty-five persons or portion thereof; (*b*) where the number of persons so employed exceeds one hundred but does not exceed five hundred there shall be one additional sanitary convenience for every forty persons or portion thereof over the first one hundred; (*c*) where the number of persons so employed exceeds five hundred there shall be one additional sanitary convenience for every sixty persons or portion thereof over the first five hundred; (*d*) at each working level a well-ventilated, screened latrine with cement concrete floor, graded and drained to a sump, shall be provided for white and coloured persons separately, and shall be kept adequately supplied with sawdust, tailings, fine ash, or other suitable absorbent; (*e*) all pails or buckets used in connexion with underground sanitary conveniences shall have close-fitting lids which can be clamped on to prevent spillage during removal to surface. (*f*) All disused workings shall be barricaded off so as to prevent liability to fæcal pollution.

161. (1) If the manager or mine overseer is unable personally to carry out the duties prescribed for a shift boss in this regulation one or more competent white persons shall be appointed to act as a shift boss or bosses. (2) Each shift boss shall take charge during a shift of a section of the underground workings of the mine. (3) Each shift boss shall be responsible for the proper observance of the requirements of these regulations by the gangers or miners working under him, and shall as soon as practicable report to the manager or mine overseer any contraventions thereof; he shall further specially report whether water is being used in accordance with the requirements of these regulations for the allaying of dust and fumes. (4) The appointment of any shift boss or bosses shall not be taken to relieve the manager or mine overseer of any personal responsibility under these regulations. (5) Each shift boss shall at least once during his shift inspect every portion of the section of the mine assigned to him in which persons are working or through which they may have occasion to pass and shall ascertain the condition thereof as regards ventilation, sanitation, the presence of gases, and the state of the hanging wall, foot-wall, and sides, and generally so far as the safety and health of persons are concerned, and more particularly as regards the observance of the regulations for the prevention of dust.

162. In every fiery mine:—(1) (*a*) A station or stations shall be appointed at the entrance to the mine and to different parts of the mine as the case may require and a competent person or competent persons appointed by the owner, agent, or manager for the purpose, not

being a contractor or contractors for getting minerals in the mine, shall within two hours immediately before the commencement of each shift inspect every part of the mine situate beyond the station or each of the stations and in which workmen are to work or pass during the shift, and shall ascertain the condition thereof so far as the presence of gas, ventilation, roof and sides and general safety are concerned. (*b*) Such inspection shall be made with a locked safety lamp. (*c*) A report specifying where noxious or inflammable gas (if any) was found present and what defects (if any) in roof or sides, and what (if any) other source of danger were or was observed shall be recorded without delay in a report book to be kept in the engine-house or office at the mine for the purpose and accessible to the workmen. Such report shall be in the form approved by the Inspector of Mines and shall be signed by and so far as the same does not consist of printed matter shall be in the handwriting of the person who made the inspection. Such book shall not be moved from the engine-house or office on surface. (*d*) In the report book above referred to the manager shall clearly define the districts to be inspected by each person under this regulation and it shall be the duty of the manager to provide that the size of each district shall not be too large to permit of its thorough inspection and of the fencing off of any places which may be found dangerous within the time allowed. Should the inspector of mines consider any district too large he may by notice in writing to the manager require that it be reduced or divided for inspection purposes. (*e*) No workman shall enter, or be permitted to enter, the mine, or any part thereof, until such mine or such part has been so examined and reported upon as safe in such report book. (*f*) In collieries in which over 100 persons are employed an inspection required by Subsections (1) (*a*) to (*e*) of this regulation shall not be made by a ganger of that portion of the mine in which he is to work during the shift. (2) A similar inspection by the manager, or by a competent person other than a ganger appointed by the manager, and having at least three years' underground experience in mines of the class of the mine inspected, shall be made in the course of each shift of all parts of the mine in which workmen are to work or pass during that shift, but it shall not be necessary to record a report of the same in a book, provided that in the case of a mine worked continuously throughout the 24 hours by a succession of shifts the report of one of such inspections shall be recorded in the manner above required. (3) In no case shall a person be considered competent to make the foregoing inspections unless he has had at least three years' practical experience in coal mining in mines of the class to be examined. (4) The white miner or ganger in charge of a section or district shall make at least three inspections of each working face in his section or district whilst the workmen are at work.

CHAPTER XV.—*Miscellaneous.*—167 (1). Coloured labourers at the end of the shift shall, as soon as possible, be brought to the surface and shall not be kept waiting unnecessarily at the shift stations or elsewhere. (2) Time tickets of coloured labourers employed under ground shall either be marked underground or, where this is impracticable, in the shelter-room at the surface. (3) At every mine, except where exempted by the Government mining engineer, adequate provision shall be made elsewhere than in the living-rooms for drying wet clothing of coloured labourers coming off shift, and also for washing and disinfecting the clothing of such labourers.

168. One or more notices on which are legibly printed simple directions setting forth the approved procedure for the immediate treatment of cases of "gassing" shall be posted in a conspicuous place in every change-house, recreation room, and accident emergency station.

169. No person shall pollute the underground workings with fæces or urine, nor wantonly misuse or foul the latrines.

170. When tailings are used for filling worked-out ground the moisture contained in such tailings shall not have a higher potassium cyanide content than ·005 per cent.

CHAPTER XXIV.—*Ambulance, &c.*—227 (1). At every main travelling shaft, except where the mine hospital is close to such shaft, an accident emergency station shall be provided. This emergency station shall be equipped with the following: Two Royal Navy stretchers or stretchers of other pattern approved by the Government mining engineer. Two or more fitted first-aid boxes of a pattern approved by the Government mining engineer. A supply of dressings and splints. One portable oxygen inhalation apparatus. One air-mask with light hose hand-pump, or fitted with reducing valve to connect with compressed air or service pipe. Two portable electric lamps. In addition to the above there shall be kept at every coal mine: two oxygen breathing apparatus of the Shamrock or other type approved by the Government mining engineer. (2) At every level on which ordinary mining operations are being conducted there shall be kept: (*a*) a box containing emetic solution, sal volatile, three or more bandages, and a card upon which are printed simple directions for treatment of cases of gassing; (*b*) at least one plank stretcher of a pattern approved by the Government mining engineer. (3) On and after the first day of January, 1913, every mining official on any mine employing not less than 500 persons within six months after his appointment shall be required to be in possession of the certificate of an ambulance association recognised by the Minister testifying that the holder has attended a course of first aid and is qualified to render first aid to the injured, with special reference to mining accidents. For the purpose of this section mining officials shall not be taken to mean the classes of persons shown on the following list with any alterations of such list as the Government mining engineer may from time to time determine: Mine overseer, shift boss, chief surveyor, mechanical engineer, electrical engineer, foreman smith, foreman carpenter, foreman fitter, chief electrician, battery manager, cyanide manager, compound manager, hospital superintendent or orderly.

278 (1). At every mine or works where cyanide is used there shall be kept in a conspicuous and convenient place a sufficient supply of a satisfactory and efficient antidote for cyanide poisoning approved by the Government mining engineer. (2) Such antidote shall be kept in a box labelled "cyanide antidote" and explicit directions for the use of such antidote shall be affixed inside the lid of the box. (3) All vessels used for the treatment with acid of zinc slimes from the cyanide process shall be fitted with mechanical agitators and hoods or other appliances of such a nature that the fumes generated in such vessel shall be carried direct to the external air. (4) An adequate supply of wholesome drinking water shall be provided in each testing-room and assay office, and this supply shall be distinctly labelled "drinking water."

279. When any person employed in or about a mine or works receives injury by accident or otherwise the manager shall be responsible that the nearest qualified medical practitioner is sent for, unless the regular medical practitioner appointed to the mine or works resides within two miles of the scene of the accident. If the injured person is unable to proceed unaided to his abode or to a hospital the manager of the mine or works shall immediately have such person conveyed to his abode or to a hospital in the safest, best, and quickest way at the expense of the owner of the mine or works.

LEISHMANIA AND MOSQUITOES.

To the Editor of THE LANCET.

SIR,—Being, owing to stress of work, somewhat behindhand in the reading of your journal, I have only just noticed the article by Professor G. Franchini on the development of "leishmania donovani in anopheles."[1]

Before attempting to fill up the "great lacuna still existing in our knowledge of the transmitting agents of Leishman's bodies," it is necessary to be acquainted with the literature on the subject. And it is evident that Professor Franchini has either never read the work which has been carried on in India or chooses to ignore it. As long ago as 1907, or rather before, Captain W. S. Patton, I.M.S., when experimenting with kala-azar and mosquitoes, found that both culex fatigans and anopheles stephensi in the endemic area are naturally infected with a species of herpetomonas (H. culicis Novy) indistinguishable from either leishmania donovani or leishmania infantum, and that the mosquitoes acquire the infection through the larval stage. Professor Franchini does not state whether his mosquitoes are naturally infected with a species of herpetomonas. Until this is known the experiments described by him are valueless. Since reading his article I myself have seen in Guindy, Madras, in culex fatigans flagellates which answer to the descriptions given by Professor Franchini, being, in fact, the flagellate and post-flagellate forms described by Patton in his account of the life-history of the flagellates seen by him in mosquitoes.[2]

Further, it is difficult to understand why Professor Franchini fed his mosquitoes on cultures in which the parasites would already be flagellates. In order to be quite sure the parasite will flagellate in the species of mosquito used he ought to have fed his mosquitoes on a case which contains the pre-flagellate forms in its peripheral blood. Concerning the transmission of kala-azar Captain Patton has infected bugs (cimex rotundatus) which show no natural flagellates by feeding them on heavily infected kala-azar patients (note, not on cultures), and in them has then shown the flagellate forms. The lacuna still to be filled up is the transmission back again to animals and so the production of kala-azar. And until this is done the complete etiology of kala-azar will still belong to the arcana of pathology. If Professor Franchini in his experiments used cultures of "leishmania infantum," as I presume he must have done, I fail to see how he can thereby claim that "the leishmania donovani can live and develop in the intestinal tract of the anopheles." I note that such is the heading of his article. Leishmania infantum and leishmania donovani are not synonymous terms.—I am, Sir, yours faithfully,

J. HAY BURGESS, M.D. Lond., M.R.C.P. Lond., F.R.C.S. Eng.,
Captain, Indian Medical Service.
St. Thomas Mount, Madras, Dec. 21st, 1911.

PS.—In support of my statements please see Scientific Memoirs, No. 27 and 31, of the Government of India by Captain Patton.

FUNGI FOUND IN TROPICAL BRONCHOMYCOSIS.

To the Editor of THE LANCET.

SIR,—In the interesting paper on bronchomycosis by Dr. A. Castellani in THE LANCET of Jan. 6th no fewer than 12 new species of endomyces are named. One of these is figured as it occurs in the sputum and in a maltose agar culture. There is nothing in the figures or in the text to suggest that the organisms are endomyces, but I shall assume that this has been proved elsewhere.

We are told that "in contrast to the usual endomyces albicans none of them liquefies gelatin." Now endomyces

[1] THE LANCET, Nov. 4th, 1911, p. 1268.
[2] Brit. Med. Jour., July 13th, 1907.

albicans (Vuillemin) is the latest name of our old friend the thrush fungus. In his original communication[1] Vuillemin only goes into botanical details, but Gedoelst,[2] who specially thanks Vuillemin in his preface for supplying information, distinctly states that this organism never liquefies gelatin. Further, it has been pointed out[3] that whereas oidium lactis liquefies acid saccharine gelatin (wort gelatin) the thrush fungus does not liquefy gelatin under any circumstances. As a matter of fact, it is rare to find any yeast or allied organism that can touch nutrient gelatin even in months. On the other hand, they generally do liquefy sugar gelatin in 3–4 weeks, and 30 days was the time indicated as a fair test at 20°–22° C. by Duclaux's work.[4] At present the statements of different authors in regard to the action of eumycetes on gelatin are often difficult to reconcile.

In the table of fermentation reactions there is an example of the rule that often holds good in these fungi—viz., an organism fermenting lactose also ferments saccharose, but not maltose. It is remarkable, however, that the organism E. pseudotropicalis ferments lactose well and only gives a trace of gas with galactose. The name E. guilliermondi naturally arrests the attention of anyone interested in saccharomycology. In any case the organism would do so as it ferments saccharose but not lævulose. To anyone accustomed to the vagaries and aliases of these organisms the table suggests that the number of species could be reduced, and the text raises a suspicion that Sac. krusei is E. pinoyi masquerading in conidial form as a yeast.

Dr. Castellani has done good service in directing attention to the pathogenic importance of a group of organisms hitherto regarded as unimportant in pathology.

I am, Sir, yours faithfully,

Acton, W., Jan. 8th, 1912. R. CRAIK, M.D. Glasg.

THOMAS *v.* BARKER.

To the Editor of THE LANCET.

SIR,—As you have revived, in a conspicuous paragraph in your last issue, the memory of the action brought against me last February, perhaps you will allow me to say a few words upon the subject? Has it ever occurred to you that it is just possible that I was blamed for the negligence of others? If you read all the evidence, can you unhesitatingly tell me that you have never more than half-suspected that I was made the object of a very great and very cruel injustice, which, had I been a younger and less successful man, might have brought about my financial and professional ruin?

Are you aware that the *sole* charge brought against me was that I had wrenched an indisputably tuberculous joint and that the only person in the room at the time of the alleged violence was a fully qualified medical man who swore that I used no force of any kind?

Do you know that one of our most eminent surgeons wrote the following words after hearing the trial from beginning to end: "I affirm that it was *impossible* for a man of Mr. Barker's education and experience to be guilty of such a blunder, ... and amongst the crowd of distinguished men and women who thronged the court anxious to bear testimony to his skill, I venture to assert there was not one who was not disgusted and indignant at the patent injustice of the verdict." It is useless for me to tell you now, as I told the court, that I was *absolutely innocent* of what was alleged against me, but I do confidently hope that before my work is finished, you, amongst other members of your profession, will understand that I was made to suffer for an offence I never committed, and that I have not entirely laboured in vain for the advancement of a neglected art which has done very much to relieve human suffering.

Faithfully yours,

Park-lane, W., Jan. 4th, 1912. H. A. BARKER.

*** We cannot admit without demur Mr. Barker's definite claim to a "professional" position. We do not know to what "education" the eminent surgeon refers as having been undergone by Mr. Barker. We publish this letter, but we would ask Mr. Barker to remember that in so doing we publish an indictment of a jury, who are entitled to be considered honest and capable.—ED. L.

THE MEDICAL PROFESSION IN FRANCE AND THE ACCIDENT INSURANCE QUESTION.

(FROM OUR SPECIAL SANITARY COMMISSIONER.)

Private Interests and Social Legislation.

IN France, as in England, the law establishes the liability of employers in the case of accidents to employees, and the former to protect themselves insure their workpeople. But for such insurance the employer would often be unable to meet his liabilities, and the injured workman would suffer in consequence. This, however, is no State insurance founded for the benefit of the community as a branch of social legislation. The insurance companies which undertake this work were brought into existence merely as speculations organised for the purpose of providing the highest possible dividends for their shareholders. As in England, in exchange for a fixed annual premium paid by the employers, they undertake to defray the employers' liabilities should an accident occur. This liability is established by the law of April, 1898, and amended by the laws of March 22nd, 1902, and March 31st, 1905. When an accident occurs the incapacity resulting entitles the victim to an allowance equal to half the wages such incapacity is likely to make him lose. If the victim dies his family is entitled to a small pension. Obviously it is in the interest of the insurance companies to meet these liabilities in the most parsimonious manner possible. There is here an acute conflict of interests which tends to defeat the object of the law. So much is this the case that the abolition of all such insurance companies is energetically demanded both by the organised working men and by the medical syndicates or unions.

In giving expression to the abuses and collecting evidence to prove that the complaints are fully justified none have been more active than Dr. Ch. Diverneresse. This evidence consists of testimony and documents, and some correspondence has been carefully photographed. Several of these photographs are now in my possession, and they clearly show the attitude and methods of certain insurance companies.

The Taxpayer Pays for the Insurance Companies.

Dr. Diverneresse explains the object of the insurance companies and then gives evidence to show to what a large extent this object is attained. The insurance companies seek to get medical men into their service on low terms. They offer a fee of 8 francs for every accident case visited, but nothing more. In these circumstances, the medical man has no motive to continue attending the patient and is glad to hand him over to the poor relief authorities who put him in the nearest municipal hospital where only 3 francs 50 centimes per day is charged for the patient. Thus, the insurance companies save their money at the expense of the taxpayer, who provides for the upkeep of the municipal hospitals. The next step is to bring to bear every kind of influence on the medical experts so that they may estimate the injury sustained at the lowest possible figure and thus reduce the amount of the damages that have to be paid. Thus the medical man employed by the insurance companies is often begged not to mention upon his certificate the fact that permanent injury is likely to result; for, unless this is done, the local tribunal cannot hold an inquiry into the circumstances of the accident. If there is no such inquiry there is no public discussion and the pension to be paid has to be settled personally with the victim. Instead of a public trial experts are appointed as arbiters, but every effort is taken by the companies to secure that these shall be favourably disposed towards the big employers and the insurance companies. Dr. Diverneresse has several letters showing that the companies actively interfere in these appointments. Here is the text of one of them:—

I have the honour of informing you that according to the new stipulations of the law of the 31st March, 1905, the magistrate of the —— District *has on our demand appointed you to examine* M. B——, victim of a labour accident which took place on the 15th November, 1905.

The Partiality of Experts.

Many cases are published giving the effect of these manœuvres, and it must be admitted that they do not redound to medical credit on first reading. But we have enough difficulty in England with regard to workmen's

insurance to make us careful of being too suspicious. Genuine differences of opinion must often occur. In one such case an expert known to favour the insurance companies but appointed by the local magistrate estimated as the result of an accident that the victim's leg was shortened by about 5 millimetres, and concluded that his wage-earning capacity had been impaired to the extent of 5 per cent. The tribunal, acting accordingly, fixed the annual pension to be paid at 63 francs. But the victim appealed against this decision. Three other experts agreed that the shortening of the leg amounted to 25 millimetres, and thereupon the court raised the pension to 382 francs. So often are such differences of opinion worked in France against the workmen, according to Dr. Diverneresse, that he advises them strongly not to present themselves before an expert unless accompanied by a medical man to watch over their interests.

The insurance companies, if on good terms with the employer, have other methods of avoiding the fulfilment of their obligations. A case is related of a workman who was injured, and the tribunal estimated that his earning capabilities had been permanently reduced in the proportion of 12 per cent. The pension allowed was based on this estimate. Thereupon the company proposed to buy up his rights by paying a sum down. This sum, of course, should have been calculated on the basis of the 12 per cent. The employer, however, threatened to discharge the workman if he did not accept a sum calculated on the basis of 8 per cent. Rather than lose his situation the workman consented thus to lose a third of the compensation to which he was entitled, but so that the President of the tribunal should authorise this reduction it was necessary to produce a medical certificate testifying that now the workman in question was suffering from incapacity equal to only 8 per cent. Before me is the photograph of the letter written on the paper of the insurance company, whose full name and address are printed on the top. The name of the doctor to whom it is addressed heads the letter. This is a literal translation of the letter:—

> We are going to send you one of our pensioners, named V——, with whom we have to come to terms for the purchase of his pension. The initial reduction was 12 per cent.; the new reduction will be 8 per cent. which we ask you to inscribe on the certificate which you will be so good as to deliver so as to enable us to come to terms.

This letter is signed by the agent of the company. It is neither more nor less than an order to estimate the damage done at 8 instead of 12 per cent. without the slightest regard to the facts of the case. In another letter, of which I have also the photographed copy, the medical man is not called upon to alter an estimate of damage done, on which there might conceivably be some difference of opinion, but he is asked to state in his certificate that the patient was cured on the 24th of the month instead of the 31st. It is urged that medical certificates given under such circumstances to oblige insurance companies are not in keeping with either science or conscience, and I am glad to believe that they are not given as frequently as they are demanded.

Pressure to Prevent the Free Choice of Medical Attendant.

The law, however, insists that the victim shall have the free choice of a medical attendant. But the companies strive by every means to prevent workmen exercising their legal right. On one side they attack and intimidate the workmen and on the other side they use much the same means against the medical practitioners. If the latter are sufficiently independent different and insidious methods of persecution may be directed against them—at least Dr. Diverneresse states that this is the case. The fact that a practitioner acquires some popularity among the working classes and is often consulted by injured workmen will be considered as a suspicious circumstance. It will be whispered around that at heart he must be an anarchist, a dangerous person, and the more wealthy inhabitants in the neighbourhood will be advised to consult someone who enjoys a better reputation in the ranks of polite society. A good case of this sort is described as occurring to a practitioner who attended most of the workmen engaged at some large works in the department of the Ardennes. The manager openly declared that he had forbidden his workpeople to call in the services of the practitioner in question when an accident occurred "because he had not fulfilled expectations in supporting the interests of the works." The interests of the works were to be supported in one instance by declaring that a patient had been cured before a certain date when this was absolutely false. Then when the independent practitioner refused to comply the manager of the works insisted that the medical fees for which his firm was responsible should be reduced by 25 per cent. This meant the trouble of legal proceedings, but the doctor won his case. After that the workmen were not only forbidden to call in this practitioner when an accident occurred but also in cases of ordinary sickness. All this was absolutely illegal, but it was done all the same.

Suggested Remedies.

Such are a few of the cases selected out of a great number to show the demoralising influence exercised by speculative insurance companies. There are more than 300,000 labour accidents in France during the course of a year. At least a quarter of these accidents necessitate the obtaining of a certificate from an expert. It will be seen at once that on the result very large sums of money are involved. The interest of the nation is not specially bound up in economising the employers' capital. The object of legislation on the employers' liability for accidents is to diminish the frequency of such accidents, and when they occur to prevent the pauperisation of the injured and their families. The State is interested in seeing that the injured receive the full amount to which they are entitled. The interest of the medical profession is that medical men shall not be influenced in their judgment by pressure brought to bear upon them either by the injured on one side or by the employers and the insurance companies on the other side. The best guarantee against pressure from the latter source is the free choice by the patient of his medical attendant. But in some places the medical practitioner is liable to persecution if he responds to such a call, and the workman on his side runs the risk of being discharged if he does not call in the medical practitioner pressed upon him. Thus is the law defeated and the injured workman defrauded. The honour of the medical profession is involved in this scandal. Fortunately, there are medical unions to take up the matter, force the question forward, and insist on the impartial fulfilment of the law. To secure this the experts consulted must be beyond all suspicion; they should not have any connexion whatsoever with insurance companies or industrial enterprises, and they should be appointed beforehand and not chosen by local magistrates after an accident has occurred. Above all, any attempt at intimidation or unfair pressure should be severely dealt with.

THE MEETING OF THE CANADIAN PUBLIC HEALTH ASSOCIATION IN MONTREAL.

(FROM OUR SPECIAL CORRESPONDENT.)

Opening Ceremony.

THE newly-formed Canadian Public Health Association held its first annual meeting in Montreal on Dec. 13th, 14th, and 15th, 1911. The Governor-General of Canada, His Royal Highness the DUKE of CONNAUGHT, became a Patron, and, accompanied by the Duchess of Connaught and the Princess Patricia, performed the opening ceremony in the Convocation Hall of the Royal Victoria College.

The Hon. R. L BORDEN, Premier of Canada, a Vice-Patron of the association, and the Hon. MARTIN BURRELL, Minister of Agriculture and a Vice-President, took part in the proceedings.

The meeting was presided over by Dr. T. W. STARKEY, President of the association, professor of hygiene at McGill University, to whose zeal much of the success of the arrangements was due. After a brief address of welcome to Their Royal Highnesses and an expression of the gratitude of the association to Lord Strathcoma, Dr. Starkey read the postscript of a letter from the Canadian High Commissioner, enclosing a cheque for $2500 (£500) for the use of the association.

The DUKE of CONNAUGHT, in an excellent speech, emphasised the need for the general public to take an intelligent interest in preventive medicine. He said: "Our idea is that what was good enough for the past generation is not good enough for the present, and to improve conditions we must teach the growing generation."

Mr. BORDEN laid stress on the fact that in the past the matter of public health in Canada had not received all the consideration it should have received, but he intimated that in the future the Federal Government would pursue a different policy in this respect.

Mr. BURRELL, Minister of Agriculture, made the announcement of the evening, to the effect that a national department of health would be created. "Speaking quite unofficially," he said, "I would say I believe the time has come when, even if it does not demand a portfolio, it should at least have a full-fledged department in the Federal Government."

Sir LOMER GOUIN, Premier of the province of Quebec, who spoke in French, also announced that the Government of the province contemplated taking forward steps with regard to sanitary matters. He said that the Government of Quebec had decided to extend its hygienic work by dividing Quebec into ten sanitary districts, an expert reporting directly to the Government for each district.

Brief addresses were also given by Dr. GUERIN, Mayor of Montreal, and by Dr. MONTIZAMBERT, of Ottawa.

Dr. MONTIZAMBERT, as the oldest sanitarian in Canada (having been appointed to an official post by Sir John MacDonald in 1866), in moving a vote of thanks to the Governor-General for opening the meeting and to the Duchess of Connaught and Princess Patricia for being present, recounted the history of sanitation in Canada.

Before leaving Victoria College the Duke and Duchess, with other guests, partook of supper in the dining-hall. It may be said that the whole proceedings passed off without a hitch, a fact which reflects great credit upon all those responsible for the arrangements.

A meeting inaugurated in such auspicious circumstances had a high ideal to reach, and so far as the serious business of the meeting was concerned its members rose to the occasion. The attendance was good, about 130 members being present, while the papers contributed were numerous and generally of a high standard. If one desired to be censorious, perhaps the criticism might be made that there was somewhat of a plethora of papers, more than 50 being contributed. This, however, certainly speaks well for the energy of those interested in health matters in all parts of the Dominion.

Papers Read.

In the first general session Colonel G. CARLETON JONES, M.D., M.R.C.S., Director-General, Medical Services, Department of Militia and Defence, Ottawa, read a paper on the Military Aspects of Sanitation, in which he pointed out that although Canada was not generally regarded as a military nation, a form of conscription was really in force, and that therefore military sanitation was of more than academic interest.

Dr. J. D. PAGE, of Quebec, dealt with medical inspection and the care of immigrants on shipboard. He said that the examination of immigrants on shipboard was largely perfunctory, and consequently more or less useless to the Canadian medical inspectors of immigrants. He pointed out that the law directed that ships' surgeons should examine immigrants carefully, but said they did not live up to this obligation. He urged that no one had better opportunities for judging of the physical and mental fitness of an immigrant than the ship's surgeon. The chief reason for this slackness on the part of ship's surgeons, according to Dr. Page, was that these were usually young men who came for a change and a cheap sea trip, and had had no training whatever in regard to the work they were supposed to perform on board ship. Of course, the fault for this state of affairs really lay with the shipowners, who would not give sufficient remuneration to attract able medical men. Dr. Page thought that if an initial salary of $1000 (£200) a year were offered an efficient class of medical men might be secured for immigrant ships. The speaker had spoken to shipowners on the subject, who had replied that so long as they could procure more men by far than they required at the present beggarly rate of wages, they saw no cause to offer superior inducements. Thus there would seem to be little hope of bettering the situation in this quarter, and some other means must be resorted to to remedy existing conditions in this respect.

Dr. P. H. BRYCE read an exceedingly able paper on the Conservation of Food by Cold, a vital subject in these days on this side of the Atlantic.

One of the most interesting sections of the meeting was that of the social workers. This might be termed the ladies' meeting, as the convener was Dr. GRACE RITCHIE ENGLAND, and most of the papers read were contributed by women. It can be asserted with truth that from all points of view these papers compared favourably with those read in the other sections, and from a purely literary standpoint they were generally superior.

The first paper read in this section, however, was by a man. Dr. GEORGE ADAMI, professor of pathology, McGill University, treated of the value of exhibitions as agents in the public health campaign. He made out a very good case for such means of popularising public health movements, and incidentally said: "The daily press to a greater and greater extent is becoming one of the most effective agents in making known the defects in conditions relating to the public health." Miss ETHEL HURLBATT, principal of the Royal Victoria College, read a paper on Work for Women as Sanitary Inspectors. She said that Canada was beginning to realise that the health and well-being of the individual involved that of the community, and that the latter was coming to see its duty in enforcing proper precautions for the care of individual lives. Miss Hurlbatt advised the employment of women sanitary inspectors in factories where women worked, as well as in many homes.

Dr. A. D. BLACKADER, professor of pharmacology and therapeutics at McGill University, discussed the important causes of high infantile mortality in large cities, and the influence exerted by milk depôts.

(To be concluded.)

BIRMINGHAM.

(FROM OUR OWN CORRESPONDENT.)

The General Hospital.

AT a meeting of the board of management on Jan. 5th a letter was read from Professor Robert Saundby resigning his post as honorary physician to the hospital. It was unanimously resolved:—

That the board, having received with great regret the resignation of Dr. Saundby, senior honorary physician, desire to record their high appreciation of the very able manner in which he has discharged his duties as honorary physician for the past 27 years, of the skill and attention he has devoted to the patients under his care, and of the interest he has taken in the welfare of the institution; that his resignation be accepted with great regret, that the post be declared vacant, and that steps be taken to fill the vacancy on Friday, Jan. 25th.

It was further resolved:—

That it be recommended at the next meeting of the governors that, in consideration of the eminent services rendered by Dr. Robert Saundby to the hospital during the past 36 years, he be appointed honorary consulting physician to the hospital.

A committee was appointed to consider what steps should be taken to commemorate Professor Saundby's services. Professor Saundby, who is the President of the British Medical Association, came to Birmingham in April, 1876, when he was appointed resident registrar and pathologist to the General Hospital. In November, 1877, he was made assistant physician, and in January, 1885, was elected honorary physician. He has thus been connected with the hospital for 36 years, and for several years has been senior physician. He is also professor of medicine in the Birmingham University, consulting physician to the Eye Hospital, and the representative of the University on the General Medical Council.

New Year Honour.

The conferment of knighthood upon Professor Bertram C. A. Windle has caused much satisfaction to his numerous friends in Birmingham, where for many years he was professor of anatomy and Dean of the medical school. Like Professor Saundby, he came to Birmingham as pathologist to the General Hospital, a post which has been successively occupied by many distinguished medical men in Birmingham and elsewhere.

Anterior Poliomyelitis.

The medical officer of health, Dr. J. Robertson, has ascertained that during 1911 there were 150 to 200 cases of anterior poliomyelitis in the city with a few deaths. In several families more than one case occurred. In October last the health committee passed a resolution ordering that the Infectious Diseases Notification Act should apply within the city for a period of two years to this disease. The resolution was submitted to the Local Government Board for approval and came into operation on Jan. 1st.

Jan 9th.

SCOTLAND.

(FROM OUR OWN CORRESPONDENTS.)

Queen Victoria's Jubilee Institute for Nurses.

THE report of the council of the Scottish branch of the Queen Victoria's Jubilee Institute for Nurses shows, as usual, an interesting record of growing work. The report refers especially to the loss sustained by the death of Dr. Joseph Bell, who had given valued services to the Scottish branch during the whole period of its existence. During the stage of initial organisation Dr. Bell had acted as vice-president of the provisional committee, and on the formation of an executive committee he was unanimously appointed chairman, the duties of which office he discharged with the utmost thoroughness until his last illness. In view of the increase in the work, the council has resolved to appoint a new committee to superintend the work done in the central training home, which included the nursing of the sick poor of Edinburgh. The office of honorary secretary of the Scottish branch has now been filled by the appointment of Lady Susan Gilmour. Thirty-six nurses have been trained in the central home during the year, while four have completed their training in Glasgow, two in Dundee, and two in Paisley. There are now 225 nursing associations affiliated to the Scottish branch of the institute, nine new branches having been affiliated during the year.

Legacy to Dundee Royal Infirmary.

At a meeting of the directors of the Dundee Royal Infirmary, held on Jan. 4th, it was intimated that the late Mrs. Euphemia Small or McGregor, widow, 3, Park-terrace, had by her settlement bequeathed the residue of her estate to the institution. It is expected that the infirmary will benefit to the extent of £900.

Montrose Asylum's New Charter.

A meeting of the Montrose Asylum board was held on Jan. 3rd, when the proposed new charter was again under discussion. At a previous meeting the asylum managers practically unanimously agreed that the appointment of auditor should be retained in the power of the board, but the representatives from Forfarshire and Kincardineshire parish councils and district lunacy boards, who initiated the scheme for representation, now informed the managers that if they insisted on a local instead of an official auditor being appointed the whole scheme might be wrecked. After considerable discussion it was resolved, by 12 votes to 5, that the auditor should be appointed by the board as heretofore, but that the appointment should be subject to the approval of the Secretary for Scotland.

Jan. 9th.

IRELAND.

(FROM OUR OWN CORRESPONDENTS.)

The Milk Commission.

THE *personnel* of the Vice-Regal Commission on Milk-supply has been changed by the resignation of Sir John Lentaigne, through stress of professional work, and the accession of Sir Stewart Woodhouse. The latter had a long experience as Local Government Board inspector, and subsequently as member of the General Prisons Board. It is unfortunate that the Commission does not include any medical officer of health experienced in the control of a milk-supply. Mr. T. W. Russell, M.P., Vice-President of the Department of Agriculture and Technical Instruction, gave important evidence a few days ago with regard both to the scarcity of milk in certain districts, and to the difficulty of preventing adulteration of milk and butter. As a remedy for the scarcity of milk he suggested that municipalities should purchase lands, to be run as dairy-farms, and so provide a public milk-supply. Some previous witnesses had suggested the use of goats' milk in districts where cows' milk could not be obtained. Mr. Russell pointed out that to provide sufficient milch goats they must be imported, and this could not be permitted because of the danger of introducing disease. He went on to give instances illustrating the difficulty of obtaining convictions and adequate penalties in the case of prosecution for adulteration or selling milk in an insanitary condition. In a recent case where it was proved that there was 25 per cent. of water in the butter a fine of 1*d.* was imposed! Fines of 10*s.* or £1 were frequently imposed by Dublin magistrates for adulteration of milk, but such penalties did no good. No punishment except imprisonment would cure this form of offence.

The Professorship of Surgery in the Royal College of Surgeons in Ireland.

Mr. William Stoker has, after many years' occupancy of the chair, resigned the professorship of surgery in the Royal College of Surgeons. Already there are several candidates in the field, including Mr. G. Jameson Johnston, surgeon to the Royal City of Dublin Hospital; Mr. William Taylor, surgeon to the Meath Hospital; and Mr. W. I. de C. Wheeler, surgeon to Mercer's Hospital.

The National University of Ireland.

Interesting changes have been made in the courses and regulations of the National University of Ireland for 1912–13. All information will be supplied from the University offices, 49, Merrion-square, Dublin (temporarily).

Vaccination Certificates.

A curious incident has occurred in the Celbridge union, where the Local Government Board has refused to sanction payment to a *locum tenens* on the ground that he does not possess a certificate in vaccination such as is prescribed by the Board. Up to a few years ago the Local Government Board recognised a certificate of instruction in vaccination given by any public vaccinator. A new rule was subsequently introduced stating that the Board would recognise only certificates granted by certain specified instructors, three or four in number. It appears that Mr. Knapp, the medical man affected in the Celbridge union, holds a certificate from a public vaccinator, but not from one recognised as giving certificates by the Local Government Board. The guardians apparently have no ground of complaint against Mr. Knapp, but they are in the difficulty that if they pay him they are liable to be surcharged. A newspaper report of the case added to the unpleasantness by referring to the lack of a "midwifery certificate" instead of a "vaccination certificate" as the cause of the trouble.

Medical Officership of the Pembroke Township.

Some controversy has arisen over the recent election of a superintendent medical officer of health of the Pembroke township. Contrary to the usual custom of public bodies in Ireland, voting was by ballot. An objection has been lodged with the Local Government Board on behalf of one of the defeated candidates. It is not yet known what action the Local Government Board will take.

Inspection of Belfast Workhouse.

Dr. E. C. Bigger and Mr. F. J. McCarthy, Local Government Board inspectors, have just reported on their inspection of the Belfast workhouse on Nov. 11th, 1911. They point out that the expenditure on out-door relief, which in 1905 was £620, has risen to £4,778 12*s.* for the year ending March 31st, 1911, and they urge the guardians to do everything in their power to keep their expenditure under this head within reasonable limits. If Whitechapel, with a large proportion of poor to the mass of the population, can reduce the numbers of those in receipt of out-door relief to 21, Belfast has no right to pay such a fabulous sum yearly. Every authority condemns this system which, in the opinion of the Royal Commission on the Poor-laws, merely "subsidises dirt, disease, and immorality." The guardians are also advised to introduce some labour test, which will ensure that able-bodied inmates—the "won't works" and the "workshys"—shall be compelled to do as much and as hard work as the ordinary unskilled labourer. The guardians are especially praised by the inspectors for their care of the consumptive poor. The White Abbey Sanatorium for Phthisis contains 265 beds, and is going to be enlarged by the erection of another pavilion, in order to carry out a much-needed improvement in classification at the Abbey Sanatorium.

Rathfriland Water-supply.

Rathfriland, one of the most important inland market towns of County Down, situated on a high hill, has decided to apply to the Local Government Board for sanction to a loan of £5000 for the formation of a water scheme from the Mourne mountains. Pure water is badly needed in the place, and the inhabitants are prepared to pay for it.

(FROM OUR OWN CORRESPONDENT.)

The Limitation of Wine-shops in France.

FOR many years hygienists on all hands have been deploring the increasing growth of alcoholism, an increase due largely to the ever-increasing number of wine-shops. The matter is complicated politically, because the wine merchants wield considerable political influence, and, moreover, their syndicate is very powerful. But in certain parts of France, in spite of and above every other consideration, the ravages of alcoholism being frightful, the necessary measures have at last been taken to limit the number of places for the sale of drink. In accordance with a legal enactment, the Mayor of Rouen, after deliberation with the Municipal Council, regulated by the following decree, dated March 7th, 1906, the opening of wine-shops in the city of Rouen: "The opening or establishment of a new wine-shop, or the reopening of an old one provisionally closed, within a radius of 150 metres as the crow flies from places of worship, cemeteries, hospitals, primary schools, colleges, and other establishments of public instruction is forbidden." A review of the effects of this ordinance during its five years of existence has just been made, with the following result: In 1904, 66 places were opened; in 1905, 80; in 1906 (the date at which this ordinance came into operation), 39; in 1907, 15; in 1908, 16; while in the last two years the opening of new places had fallen by 75 per cent. of the figure reached before the municipal by-law, which clearly establishes the efficacy of the step taken by the mayor. All mayors, if they are willing, can take similar measures, and these might effect a like drop in the sale of alcoholic liquors.

Milk Powder in Infant Feeding.

The feeding of infants has occupied during late years a considerable place in the attention of hygienists and physicians. More than ever breast-feeding has been insisted on and with some success. But, nevertheless, it often happens that for various reasons the mother is unable to suckle her child herself. Under these circumstances, different methods of artificial feeding have been studied very carefully. At the Pædiatric Society M. Aviragnet, M. Bloch, M. Michel, and M. Dobiencourt recently related their experience with another mode of alimentation—the use of dry milk or powdered milk. This dry milk can be obtained, either by desiccation of milk *in vacuo* at a moderate temperature (95° C.) or by rapid heating in the open air (120° to 140° C.). These observers have used this powder of milk in a certain number of normal nurslings as well as in other nursing children having various kinds of digestive troubles. The results have been generally remarkable, whether the powdered milk has been given to complete an insufficient breast supply or as an exclusive method of artificial feeding. In gastric dyspepsia the vomiting has usually ceased on the use of the powdered milk in very concentrated solution. In a great number of cases of the intestinal form of dyspepsia, often accompanied by wasting, the dry milk has been perfectly borne, frequently better than any other aliment. Sometimes this milk has seemed to be the only food that could be tolerated by the child. Finally, in certain acute cases of a febrile or algid toxi-infectious type and in a case of chronic urticaria, the milk powder has shown itself to be much the least toxic form of nourishment.

A Clinic for Criminal Insanity.

The Minister of the Interior has decided on the creation of a laboratory of criminal anthropology, such as has been frequently asked for by Parliament, which will constitute a true Clinic of Criminal Insanity. A Commission has just been organised, of which the dean of the Faculty of Medicine, Professor Landouzy, is one of the members, to settle on practical conditions under which this clinic can be established at the Ministry of Justice.

Responsibility for Accident to a Hospital Nurse.

The Tribunal of the Seine has recently given judgment in an interesting case. A nurse of the Hôpital St. Louis, who entered the radio-therapeutic department under Dr. Fleig on August 17th, 1906, sustained a fall, on account of which she claimed an annuity of 1400 francs (£56) by way of damages. She claimed that from the time of her entry on radio-therapeutic work her health had become damaged; that the influence of the electric rays had given rise to burns on her hands and to nervous troubles; and that on Dec. 17th, 1906, she became syncopal and fell on the heating apparatus, seriously burning her face. As a consequence of this accident, she said, and notwithstanding five years' treatment, she has remained disfigured, and her sight grows weaker from day to day, so that all work has now become impossible to her. But after the pleadings and the summing-up the President gave judgment to the effect that everything tended to show that the nurse fell, not in consequence of a simple syncope, but in an epileptic crisis, as was testified to by witnesses; that this condition could not be attributed entirely to the clinic in which she was employed, and that experts had decided that, at most, all that could be admitted was that a prolonged stay in a room in which practically constantly one or more unprotected Crookes tubes were in action had favoured neuropathic troubles in a person already predisposed to them. The court therefore declared the Administration of Public Assistance not responsible for the accident, and refused the damages claimed.

The Congress of French Alienists and Neurologists.

The Twenty-second Congress of Alienists and Neurologists of France and the French-speaking Countries will take place at Tunis this year, the week before Easter, from April 1st to 7th. The President of the Congress will be Dr. Mabille, of Rochelle; the vice-president, Dr. Arnaud; and the general secretary, Dr. Porot, of Tunis. The three questions on the orders of the day will be: Perverted Instincts, the Nervous and Mental Troubles of Paludism, and the Assistance of the Insane in the Colonies.

Etiology of Goitre.

TWO recent meetings of the Vienna Gesellschaft der Aerzte were taken up mostly by a discussion on the interesting problem of the etiology of thyroid enlargement. In this country there are several localities where this pathological condition is very frequent; as, for instance, in Tyrol, in the southern parts of the Alps, in Styria, in the Balkan provinces of Austria (Bosnia and Herzegovina), and also in the largest cities which derive their water from mountainous districts. The military authorities are much interested in the question, for the proportion of recruits rejected on account of goitre is now larger than it used to be. In certain districts there is hardly a young man without a more or less marked enlargement of the thyroid gland. Investigations by Professor Wagner von Tauregg on the correlation between idiocy, cretinism, myxœdema, and goitre have placed it beyond doubt that the latter condition is on the increase, that its effects are becoming more marked in the population, and that treatment by thyroid extract is useful only in selected cases. A paper by Staff-Surgeon Taussig was read before the above-mentioned society, in which he argued that goitre was infectious, that infection took place only after prolonged exposure to the hypothetical pathogenic agent, and that the intestinal canal was the way of entry of this agent. He also expressed the opinion that idiocy could be directly transmitted in a similar manner, and he drew attention to the investigations instituted by him in Bosnia amongst the Turkish part of the population, whose mode of living was very favourable to such transmission. Dr. von Kutschera, of the Austrian Public Health Service, also asserted that researches carried on by him in Tyrol proved the contagiousness of goitre and its allied conditions; he believed that the infection attached itself to the interiors of houses occupied by cretins and to the clothing and bedding.[1] The views expressed by these two speakers were strongly opposed by Dr. Wagner, Dr. Frankl-Hochwart, and other believers in the toxic theory, according to which the toxic or organic pathogenic agent was conveyed by water. Dr. Graf, who also took part in the discussion, said that in some places the recruits were in the habit of drinking the water from certain springs, with the result that after about four

[1] See also THE LANCET, Nov. 11th, 1911, p. 1347.

weeks of this practice they showed a marked hypertrophy of the thyroid gland which caused their rejection by the recruiting authorities of the army. When this manœuvre was successful they drank the same water for a second period of four weeks, taking the precaution to boil it previously, and the goitre disappeared as readily as it came. Dr. Graf said that he was just now making observations with such "goitriferous" water, and he was inclined to believe that sterilisation of it by ultra-violet rays was sufficient to make it incapable of producing the effects in question. In Vienna there has been a marked increase in the prevalence of goitre since water derived from high mountain springs was brought into the city in 1870, and even since 1910 when new springs were added to the previous source of water-supply, more goitres seem to be observed. The preponderance of opinion in the discussion was to the effect that the hypothesis of organic water-borne infection was the most probable one, and that a thorough investigation of the problem was very necessary.

The Rettungsgesellschaft.

The Vienna Rettungsgesellschaft (First Aid Corps), which has served as a model for nearly all other institutions of this kind all over the continent, has celebrated the thirtieth anniversary of its creation. The increase of its importance may be judged by the following figures. It took 14 years before 50,000 casualties were recorded on its books, 100,000 were reached six years later, and in another eight years the number 200,000 was recorded. At present the well-known car and signal of the corps is a distinctive and respected feature of the street traffic of Vienna, and this private society is the recipient of generous gifts and bequests quite contrary to the usual custom in this country, where it is expected that all charitable institutes shall be provided for by the State. It is, therefore, very unfortunate that this corps is just now engaged in a conflict with the "Wirtschaftliche Organisation" (organisation for upholding the interests of the medical profession). This organisation tries to provide a uniformity of all contracts between medical men and public or private corporations on the basis that no medical man may be dismissed unless there are satisfactory reasons for it; that payment be made on a reasonable scale; that the medical men shall have as full rights and privileges as any other employee in any other undertaking; and that old-age pensions be granted to the medical staff on terms similar to those adopted in State employments. The Rettungsgesellschaft, however, had been sadly lacking on all such points, and the board of management refused to allow the "organisation" to interfere, whereupon the latter body thought fit to make the public acquainted with the divergence of opinions between the board and its medical staff. The celebration has therefore been somewhat marred by internal dissensions, and all true friends of both the Rettungsgesellschaft and the medical profession hope that an amicable arrangement will soon be arrived at.

AUSTRALIA.

(FROM OUR OWN CORRESPONDENT.)

Sydney Hospital Centenary.

THE foundation-stone of the original Sydney Hospital was laid on Oct. 30th, 1811, by Governor Macquarie. A box containing gold and silver coin and a medallion of George III. was placed under the stone, and this was removed when the old building was demolished and is now in the possession of the hospital. The original buildings were in three blocks. One remains as part of the present Parliament House, one exists in the Royal Mint, and the present hospital occupies the site of the third which was the central block. The centenary celebrations were held on Oct. 30th, 1911, in the quadrangle of the hospital, which was covered in and lit by electric light for the occasion. The President welcomed the Lieutenant-Governor, the State Premier, and other visitors, who briefly spoke congratulatory sentiments.

Charge against Medical Man.

The elderly medical man, Dr. S. Peacock, who was recently sentenced to death for the murder of a young woman, and in whose case some law points were reserved, has obtained leave to appeal to the High Court for the direction of a new trial. The arguments before the State Full Court lasted more than a week and were mainly directed to whether the Chief Justice had misdirected the jury.

Venereal Disease.

The Queensland Branch of the British Medical Association recently discussed the question of venereal prophylaxis. Dr. E. S. Jackson, the President, moved:—

That this meeting of the Queensland Branch of the British Medical Association views with regret the repeal of the provisions of the Contagious Diseases Act as regards Brisbane, believing that even if the Act had not been stringently enforced it was yet productive of much good.

In a lengthy speech Dr. Jackson upheld his view and said that though there was plenty of syphilis in Brisbane, a large majority of sufferers could trace their infection to other States. The motion was seconded by the Hon. W. H. Taylor, M.D., M.L.C., who had a long acquaintance with the history of the Brisbane Act. An amendment was moved by Dr. A. Jefferis Turner to the effect that:—

This branch recognises the urgent necessity for legislative and administrative action on modern lines for the prevention of the spread of venereal diseases, such action to apply to both sexes and as far as possible to the whole State.

This was seconded by Dr. J. S. C. Elkington, chief medical officer of health, who thought there was something possible between a Contagious Diseases Act and no attempt at all, and indicated a preference for notification and segregation. After discussion the amendment was lost and Dr. Jackson's motion, with some unimportant modification, carried with only two dissentients.

Chair of Anthropology.

Dr. J. W. Barrett has offered £500 to the council of the Melbourne University as a nucleus of a fund for the endowment of a chair of anthropology in the University. There does not seem any immediate prospect of the scheme being developed as the council has no means of carrying it forward, but local interest in the subject has grown of late years under the direction of Professor R. S. A. Berry.

Personal Items.

Dr. Henry C. Maudsley has returned to Melbourne and resumed work as lecturer in medicine to the University.—Dr. W. Chisholm has resigned his position as surgeon to the Sydney Hospital and has been appointed to the honorary consulting staff.

Dec. 8th, 1911.

Obituary.

JOHN FRANCIS SUTHERLAND, M.D., C.M. EDIN., F.R.S.E.,

SENIOR DEPUTY COMMISSIONER IN LUNACY FOR SCOTLAND.

Dr. J. F. Sutherland died at his residence in Tain on Dec. 30th, 1911, as we stated last week. He was a native of Caithness and was born at Lybster in 1854. He received his medical education at the Universities of Edinburgh, Glasgow, and Paris. At Edinburgh he took the M.B. and C.M. degrees in 1878 and two years later the M.D. degree, obtaining a gold medal for his thesis. At Glasgow University he was a pupil of Lord Lister, who spoke of him as "a very distinguished member of my class," and in after years wrote: "He has laboured assiduously at the subjects of hygiene and the welfare of the insane, and the services which he has rendered have been recognised both at home and abroad as of very high order." Subsequently Dr. Sutherland went to Paris, and after holding the position of resident physician at the Hertford British Hospital returned to England and was for some years engaged in general practice. He then entered the Civil Service, and was appointed medical officer to H.M. Prison, Glasgow, by Sir William Harcourt (then the Secretary for Scotland), which position he held from 1880 to 1885. In 1887 the Marquis of Lothian appointed him consulting medical officer to the General Prison, Barlinnie. During his tenure of office at the Glasgow Prison he devoted himself actively to the study of criminology and allied subjects, and much of the modern penal reform may be attributed to his foresight and advocacy.

In 1895, on the recommendation of Sir George O. Trevelyan, he was appointed a Deputy Commissioner in

Lunacy for Scotland, and this position he held at the time of his death. In the year previous to his appointment as Deputy Commissioner he acted as secretary and member of the Departmental Committee on Habitual Offenders, Inebriates, Vagrants, and Juvenile Delinquents. The Lord Provost, Sir James Bell, who received this committee in the Municipal Buildings of Glasgow, paid a tribute to the continuous efforts of Dr. Sutherland in putting forward the case for habitual offenders of all classes in such a way that the Government could treat the "crying evil of the day" as a disease.

Dr. Sutherland attained a European reputation by his contributions to the literature of hygiene, insanity, and inebriety, and he was connected with many learned societies. He was an honorary member of the Medico-Legal Society of New York and of the Psychological Society of Moscow, and Foreign Associate of the Psychological Society of Paris. He was a Fellow of the Royal Society of Edinburgh and of the Statistical Society. He was honorary secretary of the Twelfth International Medical Congress at Moscow, honorary President of the Medico-Legal Section of the Thirteenth International Medical Congress at Paris, and secretary of the Fourteenth International Congress at Madrid. His publications include "Hospitals, their History, Construction, and Hygiene," which formed the subject of his M.D. Thesis, and which won marked attention by its clear-sighted policy at a time when hospital administration left something to be desired. "The Insane in Private Dwellings" was another of his thoughtful contributions to an important subject, as was also "Recidivism: Habitual Criminality and Habitual Petty Delinquency; a Problem in Sociology, Psycho-pathology, and Criminology." This suggestive book we reviewed in our issue of Feb. 13th, 1909, p. 468. "The Treatment of Dipsomaniacs" was the title of another of his books, and his well-known "Ambulance Vade Mecum" has gone through 30 editions, another being now in the press. He was also the author of the article on Lunacy in the Encyclopædia Medica, and contributed many articles to English and foreign journals. In 1892 he read a paper before the British Association at Edinburgh on Crime from an Economical, Statistical, and Social Standpoint, and when the British Association met in Glasgow in 1901 he contributed to the Economic Section an elaborate paper with statistical tables on the growth and geographical distribution of lunacy in Scotland.

Dr. Sutherland was a man of keen observation and marked energy. In order to make himself thoroughly acquainted with the management, construction, and sanitation of prisons, asylums, and hospitals he visited the principal cities of Europe and America. In the social and corporate life of Glasgow Dr. Sutherland was actively interested, and he assisted in the formation of the Association for Improving the Social Condition of the People. He was a deacon in the Well Park Free Church and was vice-president of the West of Scotland Free Education League. On his appointment as Deputy Commissioner, and before leaving for Edinburgh, he was entertained by the citizens of Glasgow to a complimentary dinner, when the Lord Provost paid a high tribute to his qualities. His work as Deputy Commissioner in Lunacy necessitated his travelling into almost every part of Scotland, and loving as he did an open-air life he was able to indulge in his favourite recreations of shooting and fishing.

He leaves a widow and family, his son, Dr. Halliday G. Sutherland, being well known as an authority on tuberculosis.

SOPHIA JEX-BLAKE, M.D. BERNE, M.R.C.P. IREL.,

LATE PHYSICIAN, EDINBURGH HOSPITAL AND DISPENSARY FOR WOMEN AND CHILDREN, ETC.

WITH the death of Dr. Sophia Jex-Blake, which took place at her home, Windydene, Mark Cross, Sussex, on Jan. 7th, a prominent personage has disappeared from the ranks of the British medical profession.

Sophia Jex-Blake, daughter of Thomas Jex-Blake, Proctor of Doctors' Commons, was born at Brighton in January, 1840. Intending at first to devote herself to an educational career, she became in 1858 mathematical tutor at Queen's College, London, a post which she occupied until 1861. She then undertook a tour of investigation into conditions relating to the education of women in various countries, and after traversing the continent she proceeded to America to continue her investigations there. While in America she attended the first course of lectures delivered by Dr. Elizabeth Blackwell, the pioneer American woman physician, at the New York Infirmary and College for Women.[1] Resolving to devote herself to medicine, in 1866 she commenced medical studies at Boston. In 1868 she returned to England and in the following year applied for permission to matriculate in medicine at the University of London, only to learn that the charter of that University had been so framed as to exclude women from its medical curriculum. Nothing daunted she went to Edinburgh, where, after meeting with a rebuff, she finally succeeded, through associating herself with several other ladies pursuing the same end, in getting the University to adopt regulations permitting the education of women in medicine in classes apart from the male students. After six months' uninterrupted study, however, considerable hostility was encountered, and this developed into serious persecution at the hands of the male students on their applying for permission to study clinical medicine in the Edinburgh Royal Infirmary. This hostility continued with such increasing virulence that in 1871 a regulation was passed by the Surgeons' Hall of Edinburgh which rendered impossible the attendance of women on its courses, in spite of energetic public protests to the contrary, and the University Senatus declined to intervene on their behalf. It is true that in January, 1872, the University offered to grant certificates of proficiency to women, but these would not have been registrable diplomas under the Medical Act, and consequently were useless as an avenue to the practice of medicine. An action was then brought against the University Senatus to compel it to allow the women students to finish their education and to present themselves for examination for a degree in medicine, and judgment went in their favour. This decision, however, was reversed by a bare majority of the whole Court of Appeal, the ground being taken that the admission of women to the study of medicine was illegal *ab initio*. The labours and expense of Miss Jex-Blake and her friends were brought to nothing, and they were saddled with costs. As further struggle in Edinburgh seemed hopeless, Miss Jex-Blake came to London in 1874, and took a prominent part in founding the London School of Medicine for Women. This institution was opened in October of that year, the privilege of attendance at the Royal Free Hospital being associated with it, and here her studies were completed. But even so, the difficulty of graduation faced her, and she had to go abroad to Berne, in Switzerland, in 1877, to take her degree of M.D. But her valiant championship of the rights of women in medicine had in the meantime aroused great sympathy for her and her cause, with the result that a Parliamentary agitation had caused the passage in 1876 of an Act to enable British medical qualifying bodies to open their doors to women, and later in the year of her graduation at Berne she was enabled to take the opportunity afforded through the acceptance of the Act by the King and Queen's College of Physicians of Ireland to obtain a British diploma as Licentiate and Licentiate in Midwifery of the College. Thus, after upwards of ten years' struggle against perpetually recurring obstacles she finally found herself able to register as a medical practitioner. In 1878 she settled in practice in Edinburgh, the scene of her former conflicts, where she established a dispensary for women and children, which developed later (1885) into a cottage hospital, now the Edinburgh Hospital and Dispensary for Women and Children. In 1886 the Edinburgh School of Medicine for Women was established by her, and she became its dean and lecturer on midwifery. The school was finally recognised as qualifying for graduation by the University in 1894. Dr. Jex-Blake continued in practice in Edinburgh until 1899, when she retired to spend her closing years in her native county of Sussex.

Among her literary works may be named her graduation thesis on "Puerperal Fever," "The Care of Infants," which reached its second edition in 1903, and two books respectively on "American Schools and Colleges" (1867) and "Medical Women" (second edition in 1886). She contributed papers and articles on the Medical Education of Women (Transactions of the Social Science Congress, Norwich, 1873, and a report on the same subject to the Chicago Conference in 1893), Medical Women (*Nineteenth Century*, 1887), and Medical Women in Fiction (ibid., 1893).

---

[1] Dr. Elizabeth Blackwell died in May, 1911, and an account of her work is given in THE LANCET of June 11th, 1911, p. 1657.

A MEETING OF WEST LONDON MEDICAL MEN.

A MEETING of medical practitioners residing in the area covered by the Chelsea and Kensington divisions of the British Medical Association was held in the Hammersmith Town-hall on Tuesday afternoon, Jan. 9th. Dr. F. J. SMITH was in the chair, and there was a good attendance. The declared aim of the meeting was to inaugurate a local Reform Committee within the Chelsea and Kensington divisions, and thence to spread the movement throughout all the divisions of the British Medical Association.

The functions of the proposed Reform Committee were defined by the promoters of the meeting in the following terms:—

1.—The objects of the committee shall be to secure the promotion and the passage of an Act of Parliament amending the National Insurance Act, 1911, in such a manner as to safeguard the interests of the medical profession as laid down in the "Six Point Programme" of the British Medical Association, and to carry out such reforms in the organisation and officers of the Association as may be necessary to achieve this end.

2.—Membership of the committee shall be open to all such registered medical practitioners as are (1) members of the British Medical Association; (2) eligible for membership of the British Medical Association and have signified their intention in writing to become members of the British Medical Association.

3.—Every member of the committee shall pledge himself to decline to accept medical service under the National Insurance Act, 1911, until it is amended in the manner laid down in paragraph 1.

4.—The subscription to the committee shall be the sum of 5*s.* per annum; such subscription shall be paid at such time as application for membership is made and upon the first day of January in each year for so long as necessary.

The CHAIRMAN opened the proceedings with a temperate statement of the case for organised reform. He argued that if the future inevitable negotiations were left by the profession in the same hands as hitherto there was grave danger of a second failure, because the same motives would be at work. He disclaimed any hostility to the British Medical Association; their quarrel was with the Council, whose attitude towards the measure they disapproved of. Dr. Smith supported his case by references to past events and by quotations from documents issued by the leaders of the Association. He urged that every legitimate endeavour should be made to get rid of those members of the Council who approved of the Act, so that the Council might truly represent the wishes of the profession. He read a letter from Dr. Buttar, chairman of the Kensington division, to the effect that the proper way to secure reform was by calling special meetings of the various divisions. Dr. Smith claimed that, although that was the correct constitutional course, in the urgency of the situation it seemed necessary to undertake some preliminary work of the kind they had attempted. They were now in a stronger position for requisitioning divisional meetings.

After Mr. P. C. RAIMENT (honorary secretary of the meeting) had given reasons for not waiting to see whether the regulations to be drafted by the Commissioners were acceptable to the profession, Mr. M. TOWNSEND proposed the following resolution in an effective speech:—

That this meeting of medical practitioners in the Kensington and Chelsea divisions of the British Medical Association, being profoundly dissatisfied with the recent decision of the Council of the British Medical Association in regard to the position of the medical profession under the Act, cordially approves of the proposal to form a Reform Committee of the British Medical Association on the lines suggested, and pledges itself to use its best interests to further the movement among all the divisions of the Association.

This was seconded by Mr. W. S. LEE.

Dr. G. J. CRAWFORD THOMSON, while strongly opposing the Act, advised against the premature formation of a new organisation which might still further spread disunion in the profession. His words created a considerable impression, although there was some dissent from various parts of the audience.

Mr. D. A. O'SULLIVAN also vigorously protested against the institution of a Reform Committee.

Dr. H. BECKETT-OVERY defended the action of the Council and warned the meeting against the consequences of forcibly turning them out.

The resolution when at length put to the vote was carried by a large majority, 11 voting against it.

A second resolution, proposed by Mr. E. W. LEWIS and seconded by Mr. W. KINGDON, was as follows:—

That pending the formation of the Central Executive, this meeting instructs the Provisional Executive to act as the Central Executive and to do all such acts and things as they may consider necessary to advance the principles already enunciated, and gives them power to co-opt members.

This was carried, and a third resolution, proposed by Mr. C. E. A. HUDDART, seconded by Dr. W. CULVER JAMES, empowering the election of temporary honorary secretaries for the two local divisions, was also agreed to. A vote of thanks to the Chairman was passed with acclamation.

The executive of the Reform Committee will have met before we go to press. It is their intention to draw up a manifesto stating the objects and methods to be adopted by the Committee, and this, we learn, will be issued to the daily press.

Medical News.

UNIVERSITY OF OXFORD.—The following candidates have been successful in the undermentioned examinations:—

FIRST B.M. EXAMINATION.

Organic Chemistry.—E. W. Bowell, J. M. H. Hardman, W. Champneys, G. R. Cowie, G. Donald, S. C. Dyke, G. I. Evans, G. T. Gilmette, F. G. Hobson, T. L. Ormerod, G. Perkins, O. S. Phillips, A. H. Plummer, S. S. L. Steyn, S. C. Varley, J. P. S. Walker, and A. L. Watts.

Human Anatomy and Human Physiology.—J. D. Batt, L. R. Broster, C. M. Burrell, G. Cranstoun, L. Gameson, F. C. Gladstone, C. W. B. Littlejohn, G. P. Selby, and J. F. West.

SECOND B.M. EXAMINATION.

Materia Medica and Pharmacology.—W. H. Bleaden, A. L. Pearce Gould, D. B. I. Hallett, A. Jackson, and G. Stanger.

Pathology.—G. E. Beaumont, G. W. Carte, W. A. Cooke, W. J. Hart, S. Hibbert, A. Juett, W. R. Reynell, E. Scott, P. T. Spencer-Phillips, and E. H. Udall.

Forensic Medicine and Public Health.—W. H. Bleaden, C. H. Budd, N. G. Chavasse, T. B. Heaton, D. P. MacDonald, E. G. Martin, W. J. Oliver, W. J. Pearson, S. S. Strahan, G. H. Varley, W. E. Waller, and J. A. Wood.

Medicine, Surgery, Midwifery.—C. F. Beevor, W. H. Bleaden, P. H. C. Fowell, T. B. Heaton, W. J. Oliver, W. J. Pearson, H. W. Scott-Wilson, S. S. Strahan, C. J. G. Taylor, and W. E. Waller.

The following degrees have been conferred:—

D.M.—H. C. G. Semon.

B.M. and B.Ch.—J. A. Noble, W. J. Pearson, C. J. G. Taylor, W. J. Oliver, W. W. Wagstaffe, W. H. Bleaden, and T. B. Heaton.

At a meeting of the Board of Faculty of Medicine held on Dec. 9th, 1911, the following resolution was passed:—

That the Radcliffe Infirmary, Oxford, be a hospital approved by the Board of Faculty of Medicine for carrying on post-mortem work by students, provided that no student be signed up for this course unless he has (*a*) passed the First B.M. Examination or has taken the Final Honour School of Physiology; (*b*) personally taken part in the actual performance of not less than ten post-mortem examinations; (*c*) regularly attended post-mortem examinations at the Radcliffe Infirmary during not less than two full terms.

EXAMINING BOARD IN ENGLAND BY THE ROYAL COLLEGES OF PHYSICIANS OF LONDON AND SURGEONS OF ENGLAND.—The following are the names of the candidates who were approved at the First Professional Examination held on Jan. 2nd, 3rd, 4th, and 5th in the subjects specified:—

Chemistry and Physics.—Thomas Burton Bailey, Cambridge; John Leycester Dudley Buxton, University College; Henry George Richmond Canning, Portsmouth Grammar School; Oliver Francis Conoley, London Hospital; Frank Barwell Matthews, Middlesex Hospital; Ralph George Mayer, Guy's Hospital; Reginald Stanley Millar, Guy's Hospital; Arthur Llewellyn Spencer Payne, Simon Langton School, Canterbury; Trefor Hughes Rhys, University College, Cardiff; Edwin John Goswycke Sargent, St. Bartholomew's Hospital; and Robert Ockleston Townend, London Hospital.

Chemistry.—Henry Searle Baker, St. Bartholomew's Hospital; Gideon Albertyn Beyers, St. Bartholomew's Hospital; Edwin Alfred Clegg, Middlesex Hospital; Leonard Henry Dardier, London Hospital; John Turnbull Thomson Forbes, Guy's Hospital; William Vincent Gabe, Middlesex Hospital; Wilhelm Otto Holst, Middlesex Hospital; Henry David Llewellin Jones, St. Mary's Hospital; Theodore Louis Kan, King's College; Guy Kinneir, St. Bartholomew's Hospital; William Ulic Desmond Longford, St. Bartholomew's Hospital; Rupert Idris Rhys, University College, Cardiff; George Cuthbert Robinson, St. Thomas's Hospital; George William Wheldon, Guy's Hospital; and Harold Ernest Poerpoint York, St. Bartholomew's Hospital.

Physics.—Reginald George Joseph Charlesworth, Charing Cross Hospital; David MacMurray Dickson, St. Thomas's Hospital; Claude Henry Fischel, Middlesex Hospital; Reginald Fitzroy Jarrett, London Hospital; Roy Dyson Langdale-Kelham, University College; Frederick Gilbert Laughton Scott, Oxford University; Mian Mohammad Shaffi, London Hospital; Charles Montague Slaughter, St. Thomas's Hospital; and Arthur Sunderland, Charing Cross Hospital.

Biology.—Douglas Harris Anthony, St. Mary's Hospital; Noel Arthur Hamilton Barlow, Guy's Hospital; Antoun Bishara, Cairo and St. Thomas's Hospital; Leslie Graham Blackmore, Middlesex Hospital; George Lambert Cutts, Guy's Hospital; Gauri Dayal, Bombay and Manchester Universities; Alfred Beresford Dummere, London Hospital; John Henry Cox Eglington, Bristol University; John Turnbull Thomson Forbes, Otago University and Guy's Hospital; William Norman Harrison, St. Mary's Hospital; Charles Gordon Hooper, King's College; Reginald Fitzroy Jarrett, London Hospital; Charles Hanmer Jenkins, London Hospital; Henry David Llewellin Jones, St. Mary's Hospital; Paul Ellis Rustat Kirby, Brighton Technical School; Eldon Munro Litchfield, New Zealand University and Guy's Hospital; Reginald Stanley Millar, Guy's Hospital; Sadek Girgis Moftah, Cairo and London Hospital; Lionel Watson Moore, Guy's Hospital; George Vaughan Richards, Guy's Hospital; Edwin John Goswycke Sargent, St. Bartholomew's Hospital; Ram Singha, Punjab University and London Hospital; Eric Lionel Stephenson, London Hospital; Ernest Wayte Terry, Manchester University; Robert Ockleston Townend, London Hospital; Cecil Pembrey Grey Wakeley, King's College; and Henry George Watters, London Hospital.

ROYAL COLLEGE OF SURGEONS OF ENGLAND.—At the Preliminary Science Examination for the Licence in Dental Surgery on Jan. 2nd, 4th, and 5th the following candidates were approved in the subjects indicated:—

Chemistry and Physics.—Lawrence Barnard Carlton, Birmingham University; Louis Edmund Claremont, Royal Dental Hospital; Donald Clewer, Brighton Technical College; William Edwin Dodd, Wandsworth Technical Institute; Herbert Reginald Evans, Royal Dental Hospital; Norman Leigh Evans, Manchester University; Gerald Mackenzie Hickley, Westminster Hospital and King's College; Kenneth Fergus McAlpin, Wandsworth Technical Institute; Joshua Laurence Oates, Guy's Hospital; Herbert Percy Parkes, Guy's Hospital; Reginald Jack Pickett, Guy's Hospital; Maurice Oliver Simpson, Birkbeck College and St. Paul's School; and Marjorie Jane White, Bristol University.

Chemistry.—Frederick James Arbery, Charing Cross and Royal Dental Hospitals; Harry Edward Attkins, Birkbeck College; Kenneth Charles Brough, Guy's Hospital; Ellis Gardner Browne, Royal Albert Memorial College, Exeter; Stephen Alphonsus McCormack, Queen's College, Belfast; Edgar William Smith, Polytechnic Institute; Arthur Herbert Virgin, Bristol University; and Frank Edward Welton, Municipal Technical College, Hull.

Physics.—Harold Beddoes, Birmingham University; Frank Briggs Cullen, University College, Nottingham; Edmund Dinsmore, Polytechnic Institute and Charing Cross Hospital; Maurice George Henry, Guy's Hospital; Joseph James Lackett Hollington, Brighton Technical College; Edgar Clarence Lewis, Guy's Hospital; Fairman John Ordish, Guy's Hospital; Tom Geoffrey Melsome Parker, Middlesex Hospital; and Willem Jacobus Rousseau Viljoen, Guy's Hospital.

UNIVERSITY OF BIRMINGHAM: FACULTY OF MEDICINE.—The following is the list of successful candidates at examinations held in December, 1911:—

Degrees of Bachelor of Medicine and Bachelor of Surgery (Final).—Class II.: James Henry Bampton, Robert Baxendell Coleman, Christopher Charles Cole Court, and Percy Alfred Newton.

Diploma in Dental Surgery (Final).—John Jessop and Edgar George Jones.

Third Examination for the Diploma in Dental Surgery (Anatomy and Physiology, and Dental Anatomy and Dental Histology).—Percy Ashton (Anatomy, Physiology).

First Examination for the Diploma in Dental Surgery (completed the Examination).—Harold Gordon Stewart Thornton.

ROYAL MICROSCOPICAL SOCIETY.—At a meeting held on Dec. 20th, 1911, Mr. H. G. Plimmer, the President, being in the chair, Mr. Rousselet described a reflecting microscope by John Cuthbert, which had been presented to the society by the committee of the Quekett Microscopical Club. Mr. Rousselet traced the history of the reflecting microscope from 1672, when Isaac Newton first suggested its construction to the Royal Society, down to 1827–8 when Cuthbert, at the suggestion of Dr. Goring, produced the design exhibited. An address of much physiological interest was then delivered by Dr. F. Shillington Scales. Taking for his subject the Photomicrography of the Electrical Reaction of the Heart, he said at the outset that the multiplicity of details and precautions requiring attention in this method of observation would probably prevent it from coming into general use for clinical purposes, and that it would not supersede auscultation, percussion, blood counts, blood pressure records, and skiagraphy. The physiological basis of the method was the fact that in muscular contraction the portion A undergoing contraction was at a higher electrical potential than the relaxed portion B, and there was deflection of a galvanometer brought into a circuit uniting two such portions of a muscle. When the contraction passed from A to B the potential of B exceeded that of A, and in the galvanometer there was now a deflection in the opposite direction. These minute differences of potential could only be detected by Einthoven's string galvanometer, an instrument of the moving coil type in which the ordinary moving coil was replaced by the "string"—a quartz fibre 2 or 3μ in diameter and coated with silver to render it a conductor of electricity. The indications of the galvanometer were recorded by the movement of a spot of light reflected from the instrument, the adjustment used by Dr. Scales being such that a deflection of one centimetre corresponded to a difference of potential equal to one millivolt. The electrodes forming the galvanometer circuit are not applied to the body in the neighbourhood of the heart. They may be in many positions, but to facilitate comparison of results three principal "leads" have been agreed on—namely, from the right hand to the left hand, from the right hand to the left foot, and from the left hand to the left foot. In the case of the human subject the individual is not in any way disturbed as he lies in bed. The electrical connexions are made by metal plates applied to the above-mentioned regions, and wires attached to these plates convey the current to the galvanometer, which need not be in the same building as the patient, but may be in a distant place if the necessary wires are provided. Cardiograms representing a variety of organic lesions of the heart were shown as lantern pictures; one of them was remarkable from the fact that it indicated the existence of ventricular fibrillation, and Dr. Scales was able to predict the imminent death of the patient from the movements of the galvanometer observed in a building at a considerable distance. Many cardiograms were also exhibited showing the effects produced by various drugs on the heart of the lower animals, including the action of muscarine and adrenalin in the frog, and adrenalin, pilocarpine, atropine, chloral hydrate, chloroform, and squill in the cat.

THE BEIT FOUNDATION FOR MEDICAL RESEARCH.—At a recent meeting of the trustees of the Beit Memorial Fellowships for Medical Research the following were elected to Fellowships: P. G. E. Bayou, doctor of medicine in the University of Würzburg, late medical officer for sleeping sickness investigations in Uganda. Proposed research: Investigation on the streptothrix stages of various acid-fast germs (to be carried out at the Lister Institute and, if possible, at a leper camp). E. V. Cooper, B.Sc. Lond., Jenner Memorial Research Scholar. Proposed research: Investigation of the protective and curative properties of selected foodstuffs and other substances against beri-beri (to be carried out at the Lister Institute). Elizabeth T. Fraser, M.B., Ch.B. Glasg., assistant bacteriologist to the Glasgow Royal Infirmary. Proposed research: Investigation of the value of the complement fixation test in tuberculosis as a guide to diagnosis and treatment (to be carried out at the laboratories of the Royal Infirmary, Glasgow). G. Graham, M.B. Cantab., late house physician at St. Bartholomew's Hospital. Proposed research: Metabolism in health and disease (to be carried out at St. Bartholomew's Hospital and at Munich). J. A. Gunn, M.D., D.Sc. Edin., F.R.S.E., second assistant in materia medica department of the University of Edinburgh. Proposed research: Investigation of the toxicity and trypanocidal action of arsen-lecithide, of the action of hormaline on the uterus as a possible substitute for ergot, and of natural immunity to certain glucosides (to be carried out at University College, London). W. H. Harvey, M.D. Toronto, Cambridge University. Proposed research: Investigation of the pathological condition of kidneys brought about by products of putrefaction in alimentary canal (to be carried out in the Pharmacological Laboratory of the University of Cambridge). J. L. Jona, M.B. Melbourne, D.Sc. Adelaide, assistant lecturer and demonstrator in physiology in the University of Melbourne. Proposed research: Investigation of the toxæmias attendant on pregnancy and childbirth (to be carried out at the Lister Institute). R. N. Norris, M.Sc. Manchester, engaged in research work at Manchester. Proposed research: Investigation of the formation and metabolism of glycogen in the organism and its bearing on diabetes (to be carried out at the Lister Institute). C. H. O'Donoghue, B.Sc. Lond., assistant to Jodrell Professor of Zoology at University College, London. Proposed research: Development, morphology and physiology of mammary apparatus (to be carried out at University College, London). C. C. Twort, M.B., Ch.B. Aberd., research worker at the Brown Institution and at the Pasteur Institute. Proposed research: Investigation of the relation of immunity reactions in Johne's disease of cattle to leprosy, and to human, bovine, and avian tuberculosis (to be carried out at the Brown Institution). Each fellowship is of the annual value of £250, and the usual tenure is for three years with a possible extension of time in exceptional cases of an additional twelve months.

A dinner under the auspices of the Joint Committee of Medical Officers Associations, consisting of representatives from the following associations and societies—Certifying Factory Surgeons, Metropolitan Water Board Surgeons, Medical Officers of Health, Police Surgeons, Poor Law Medical Officers, Postal Medical Officers, and Public Vaccinators—will be held at the Holborn Restaurant on Friday, Jan. 19th, at 7 30 for 8 P.M., with Mr. W. G. Bott in the chair. Tickets 5*s*. 6*d*., exclusive of wine. Members of the constituent associations willing to attend are requested to send their names to the honorary secretary, Mr. D. A. Belilios, 109, Queen's-road, Wimbledon.

COLONIAL MEDICAL SERVICES.—*West African Medical Staff:* Dr. J. G. Copland and Dr. O. G. F. Luhn, medical officers, Southern Nigeria, have resigned; Dr. A. Bremner, medical officer, Northern Nigeria, has been transferred to Sierra Leone; and the following appointments to the staff have been notified: Dr. W. I. Martyn-Clark and Dr. E. J. Wyler (Southern Nigeria). *Other Colonies and Protectorates:* Dr. W. Gilfillan has been selected for appointment as assistant medical superintendent of the Lunatic Asylum, Trinidad; Mr. E. H. Smith has been selected for appointment as supernumerary surgeon on the medical staff, Trinidad; Dr. W. H. C. Patrick and Dr. J. H. Cooke have been selected for appointment as district medical officers in Cyprus; Mr. J. G. Morgan has been selected for appointment as medical officer in Nyasaland; Mr. T. S. Davies has been selected for appointment as supernumerary medical officer in the Leeward Islands; and Dr. E. K. Lomas has been selected for appointment as medical officer in the Straits Settlements.

DONATIONS AND BEQUESTS.—The Chelsea Hospital for Women has received £250 from the executors of the late Mrs. Barnato, given under the exercise of their discretionary powers.—The After-Care Association for Poor Persons Discharged Recovered from Asylums for the Insane, Church House, Westminster, has received donations of £20 from the Clothworkers' Company and £10 10*s*. from the Skinners' Company.—Sir Charles Gold has given a donation of £1000 to the Bishops Stortford Hospital as a memorial to the late Lady Gold, who was a native of the town of Bishops Stortford.—The executors of the late Mrs. C. M. Barnato have made a grant of £1000 to the special ward for women and children at the Middlesex Hospital.—The late Mr. Isaac Gilman, of Warrington, has left by will £1000 each to the Warrington Infirmary, the Warrington District Nursing Association, and the Manchester Royal Infirmary, free of duty. On the death of his cousin and sister-in-law, the Warrington Infirmary will receive £2000 and the Altrincham Provident Dispensary and Hospital £1000.

LITERARY INTELLIGENCE.—Messrs. J. and A. Churchill have in the press a work on "Microbiology for Agricultural and Domestic Science Students," by various contributors. It is edited by Charles E. Marshall, professor of bacteriology and hygiene in the Michigan Agricultural College. Other books which will shortly be issued by this firm are: "Diseases of the Stomach, with Special Reference to Treatment," by Charles D. Aaron, Sc.D., M.D., professor of gastro-enterology and adjunct professor of dietetics in the Detroit College of Medicine; "Who's Who in Science, 1912," edited by H. H. Stephenson—an international biographical directory of the world's leading scientists; and "The Annual Tables of Constants and Numerical Data: Chemical, Physical, and Technological," under the authority of the International Congress of Applied Chemistry. The tables are intended to contain all the numerical data likely to be of interest in connexion with chemistry, physics, and allied sciences to be found in the most recent literature.

HENRY SAXON SNELL PRIZE.—The Henry Saxon Snell Prize, which was founded to encourage improvements in the construction or adaptation of sanitary appliances by a legacy left by the late Henry Saxon Snell, will be offered in the year 1912 by the Royal Sanitary Institute for an essay on "Suggestions for Improvements in the Ventilating, Lighting, Heating, and Water-supply Appliances and Fittings for an Operating Room and its Accessory Rooms for a General Hospital of 400 Beds where there are no Students." The prize will consist of £52 10*s*. and the silver medal of the Royal Sanitary Institute. The essay must consist of not more than 5,000 words, and must be delivered before 4 P.M on or before August 30th, 1912, addressed to the Secretary of the Royal Sanitary Institute, 90, Buckingham Palace-road, London, S.W. Should none of the essays be considered of sufficient merit or importance to deserve the prize offered the council reserves the right of withholding the award. Full particulars, including information with regard to points with which essays must deal, can be obtained from the Secretary at the Institute.

BOOKS, ETC., RECEIVED.

BAILLIÈRE, TINDALL, AND COX, London. (Published for DEPARTMENT OF EDUCATION, SUDAN GOVERNMENT, Khartoum.)

Second Review of Some of the Recent Advances in Tropical Medicine, Hygiene and Tropical Veterinary Science. Being a Supplement to the Fourth Report of the Wellcome Tropical Research Laboratories at the Gordon Memorial College, Khartoum. By Andrew Balfour, M.D., B.Sc., F.R.C.P. Edin., D.P.H. Camb., Director, and Captain R. G. Archibald, M.B., R.A.M.C., attached E.A., Pathologist and Assistant Bacteriologist, in Collaboration with Captain W. B. Fry, M.R.C.S., L.R.C.P., R.A.M.C., attached E.A., Protozoologist and Assistant Bacteriologist, and Captain W. R. O'Farrell, L.R.C.P. & S.I., R.A.M.C. Price 15*s*. net.

CASSELL AND CO., LIMITED, London, New York, Toronto, and Melbourne.

British Red Cross Society Training Manual No. 3. Issued with the Approval of the War Office. By James Cantlie, M.A., M.B., F.R.C.S., V.D., Hon. Surgeon-Colonel, R.A.M.C. (T.F.). Price not stated.

Essays on Duty and Discipline. A Series of Papers on the Training of Children in Relation to Social and National Welfare. Price 3*s*. net.

A System of Surgery. Edited by C. C. Choyce, B.Sc., M.D., F.R.C.S., Dean of, and Teacher of Operative Surgery in, the London School of Clinical Medicine (Post-Graduate). Pathological Editor, J. Martin Beattie, M.A., M.D., C.M., Professor of Pathology and Bacteriology, and Dean of the Faculty of Medicine, in the University of Sheffield. In three volumes. Volume I. Price 21*s*. net.

CHURCHILL, J. AND A., London.

Poliomyelitis in Relation to the Spread of Infection by Schools. By Frederick E. Batten, M.A., M.D., F.R.C.P. Issued by the Medical Officers of Schools Association. Price 1*s*. net.

FROWDE, HENRY, Oxford University Press, London, Edinburgh, New York, Toronto, and Melbourne.

On Bronchial Asthma, its Pathology and Treatment. By J. B. Berkart, M.D., late Physician to the City of London Hospital for Diseases of the Chest. Revised and abridged. Third edition. Price 5*s*. net.

LEWIS, H. K., London

Stepping Stones to Health on the Nile. By Frederick W. Saunders, M.B., B.C. Cantab., late Superintendent Medical Officer of the Luxor Hospital, Luxor; Member of the British Climatological Society. Price 1*s*. net.

MACLEHOSE, JAMES, AND SONS, Glasgow.

The Growth of Bone: Observations on Osteogenesis. An Experimental Inquiry into the Development and Reproduction of Diaphyseal Bone. By William Macewen, F.R.S. Price 10*s*. net.

MAYNE (ALEXANDER) AND BOYD, 2, Corporation-street, Belfast.

Applied Anatomy of the Lungs and Pleural Membranes, with Special Reference to the Apical Region of the Chest. By J. Stuart Dickey, M.D., B.Ch., Senior Demonstrator of Anatomy, the Queen's University of Belfast. Price 5*s*. net.

ROCKEFELLER INSTITUTE FOR MEDICAL RESEARCH, Sixty-Sixth Street and Avenue A, New York, U.S.A.

Studies from the Rockefeller Institute for Medical Research. Reprints. Vol. XIII. Price not stated.

SANITARY PUBLISHING COMPANY, LIMITED, 5, Fetter-lane, London, E.C.

The Sanitary Record Year Book and Diary, 1912. Price 2*s*. 6*d*. net.

Pocket Notes and Remembrancer for Sanitary Inspectors and all engaged in Public Health Work. By J. T. Cowderoy, Chief Sanitary Inspector, Borough of Kidderminster. Fourth edition, revised and enlarged. Price 2*s*. net.

SIMPKIN, MARSHALL, HAMILTON, KENT, AND CO., LIMITED, London.

Sexual Disease and its Medical Prevention. By H. N. Robson, M.R.C.S. Eng., L.R.C.P. Lond. Third edition. Price 3*s*. 6*d*. net.

THRIFT PUBLISHING COMPANY, 141, Broadway, New York City.

The Mortality of Alcohol. A Statistical Approximation of the Deaths in the United States in Which Alcohol May Figure as a Causative or Contributory Factor. By Edward Bunnell Phelps, M.A., F.S.S. Reprinted from The American Underwriter Magazine and Insurance Review, Vol. XXXVI., No. 1 (September, 1911). Price $2.00.

UNIVERSITY PRESS, Aberdeen.

University of Aberdeen. Subject Catalogue of the Phillips Library of Pharmacology and Therapeutics. 615. Price not stated.

WOODALL, MINSHALL, THOMAS AND CO., Caxton Press, Oswestry. (REGISTRAR OF THE UNIVERSITY OF WALES, UNIVERSITY REGISTRY, Cathays Park, Cardiff.)

The Calendar of the University of Wales for the Academic Year, 1911-1912. Price not stated.

Appointments.

Successful applicants for Vacancies, Secretaries of Public Institutions, and others possessing information suitable for this column, are invited to forward to THE LANCET Office, directed to the Sub-Editor, not later than 9 o'clock on the Thursday morning of each week, such information for gratuitous publication.

CRAWFORD, W. T., M.D. Edin., has been appointed Medical Officer to the Workhouse and Children's Home and District Medical Officer for Worksop.

DUNCAN, F. J. L., M.B., M.S. Glasg., has been appointed Certifying Surgeon under the Factory and Workshop Act for the Stromness District of the county of Orkney.

FLEMING, G., M.B., C.M. Edin., M.R.C.P. Edin., has been appointed Medical Officer to Crooksbury Sanatorium, Farnham, Surrey.

GREIG, F. C., M.R.C.S., L.R.C.P. Lond., has been appointed House Physician at University College Hospital.

HOPKINS, H. L., M.B., B.S. Lond., M.R.C.S., L.R.C.P. Lond., has been appointed House Physician at the Derbyshire Royal Infirmary.

KENNEDY, THOMAS, has been appointed House Surgeon at the Fermanagh County Hospital.

LEIGH, W. H., L.R.C.P. Lond., M.R.C.S., has been appointed Certifying Surgeon under the Factory and Workshop Act for the Westhoughton District of the county of Lancs.

SMALLEY, A. ASHTON, M.B., Ch.B. Vict., M.R.C.S., L.R.C.P. Lond., has been appointed House Surgeon at the Derbyshire Royal Infirmary.

TAYLOR, J., M.R.C.S., L.R.C.P. Lond., has been appointed Obstetric Assistant at University College Hospital.

TONKS, J. W., M.R.C.S., L.R.C.P. Lond., has been appointed House Surgeon at University College Hospital.

VAUGHAN, A. L., L.R.C.P. Lond., M.R.C.S., has been appointed Certifying Surgeon under the Factory and Workshop Act for the Diss District of the county of Norfolk.

WELCH, H. V., M.B., B.S. Lond., M.R.C.S., L.R.C.P. Lond., has been appointed House Surgeon at the Derbyshire Royal Infirmary.

WILLIAMS, O. E., M.R.C.S., L.R.C.P. Lond., has been appointed Assistant House Surgeon at the Derbyshire Royal Infirmary.

Vacancies.

For further information regarding each vacancy reference should be made to the advertisement (see Index).

BATH, EASTERN DISPENSARY.—Resident Medical Officer, unmarried. Salary £130 per annum, with rooms, attendance, &c.

BIRMINGHAM AND MIDLAND EYE HOSPITAL.—Resident Surgical Officer. Salary £70 per annum, with apartments, board, and attendance.

BIRMINGHAM GENERAL HOSPITAL.—Honorary Physician.

BIRMINGHAM INFIRMARY, Dudley-road.—Pathologist. Salary £250 per annum.

CAMBRIDGE, ADDENBROOKE'S HOSPITAL.—Second House Surgeon. Salary £80 per annum, with board, residence, and laundry.

CROYDON GENERAL HOSPITAL.—Junior House Surgeon. Salary £75 per annum, with board, laundry, and residence.

CROYDON MENTAL HOSPITAL, Upper Warlingham, Surrey.—Pathologist and Third Assistant Medical Officer. Salary £200 per annum, with quarters, board, and laundry.

EDINBURGH UNIVERSITY.—Examiner in Midwifery.

EVELINA HOSPITAL FOR SICK CHILDREN, Southwark, London, S.E.—Second Anæsthetist. Salary 12 guineas per annum. Also Surgeon to Out-patients.

GLOUCESTER COUNTY ASYLUMS.—Assistant Medical Officer, unmarried. Salary £150 per annum, with rooms, rations, laundry, and attendance.

GREAT NORTHERN CENTRAL HOSPITAL, Holloway-road, N.—House Surgeon and House Physician for six months. Salary at rate of £40 per annum, with board, lodging, and laundry.

GUILDFORD, ROYAL SURREY COUNTY HOSPITAL.—House Surgeon. Salary £75 per annum, with board, residence, and laundry.

HACKNEY UNION INFIRMARY, High-street, Homerton, N.E.—Two Assistant Resident Medical Officers. Salary £120 per annum, with rations, apartments, and attendance.

HARTSHILL, STOKE-ON-TRENT, NORTH STAFFORDSHIRE INFIRMARY.—House Surgeon. Salary £100 per annum, with apartments, board, and washing.

HELLINGLY, EAST SUSSEX COUNTY ASYLUM.—Third Assistant Medical Officer, unmarried. Salary £160 per annum, with board, apartments, washing, and attendance.

HITHER GREEN, S.E., PARK HOSPITAL FOR CHILDREN.—Senior Assistant Medical Officer. Salary £250 per annum, with board, lodging, and washing.

HOSPITAL FOR CONSUMPTION AND DISEASES OF THE CHEST, Brompton.—House Physician for six months. Salary 30 guineas.

LANCASTER, BOROUGH OF.—Medical Officer of Health. Salary £400 per annum.

LARBERT, STIRLING DISTRICT ASYLUM.—Second Assistant Medical Officer. Salary £130 per annum, with board, &c.

LEAMINGTON SPA, WARNEFORD, LEAMINGTON, AND SOUTH WARWICKSHIRE GENERAL HOSPITAL.—Junior Resident Medical Officer. Salary £85 per annum, with residence, board, and laundry.

LEICESTER INFIRMARY.—Assistant House Physician and Assistant House Surgeon for six months. Salary in each case at rate of £80 per annum, with board, apartments, and washing.

LIVERPOOL WORKHOUSE HOSPITAL, Brownlow Hill.—Resident Assistant Medical Officer. Salary £100 per annum, with apartments, &c.

LONDON LOCK HOSPITAL AND RESCUE HOME, Harrow-road, Paddington, W.—Honorary Dental Surgeon to Female Hospital and Rescue Home.

LONDON TEMPERANCE HOSPITAL.—Assistant House Surgeon for six months. Salary at rate of £105 per annum. Also Medical Registrar. Salary at rate of 40 guineas per annum.

MACCLESFIERD GENERAL INFIRMARY.—Junior House Surgeon. Salary £60 per annum, with board and residence.

MARGARET-STREET HOSPITAL FOR CONSUMPTION AND DISEASES OF THE CHEST, 26, Margaret-street, W., FAIRLIGHT SANATORIUM FOR MEN, AND MARGARET-STREET SANATORIUM FOR CHILDREN.—Honorary Assistant Physician.

MOUNT VERNON HOSPITAL FOR CONSUMPTION AND DISEASES OF THE CHEST, Hampstead and Northwood.—House Physician at Northwood. Salary £75 per annum, with board, residence, and washing.

NATIONAL HOSPITAL FOR THE PARALYSED AND EPILEPTIC, Queen-square, Bloomsbury.—Resident Medical Officer. Salary £100 per annum, with board and residence.

NORTHAMPTON GENERAL HOSPITAL.—House Surgeon. Salary £90 per annum, with apartments, board, washing, and attendance.

PADDINGTON GREEN CHILDREN'S HOSPITAL, London, W.—Honorary Physician to Out-patients.

POPLAR HOSPITAL FOR ACCIDENTS, Poplar, E.—Assistant House Surgeon for six months. Salary at rate of £80 per annum, with board and residence.

QUEEN'S HOSPITAL FOR CHILDREN, Hackney-road, Bethnal Green, E.—Surgeon-in-Charge of Ear, Nose, and Throat Department.

ROYAL FREE HOSPITAL, Gray's Inn-road, W.C.—Female Curator. Salary £50 per annum.

ROYAL LONDON OPHTHALMIC HOSPITAL, City-road, E.C.—Senior House Surgeon. Salary at rate of £100 per annum, with board and residence.

ST. BARTHOLOMEW'S HOSPITAL.—Physician.

ST. PAUL'S HOSPITAL FOR SKIN AND URINARY DISEASES, Red Lion-square, W.C.—Clinical Assistant.

ST. PETER'S HOSPITAL FOR STONE, &c., Henrietta-street, Covent Garden, W.C.—Junior House Surgeon for six months. Salary at rate of £50 per annum, with board, lodging, and washing.

SCARBOROUGH HOSPITAL AND DISPENSARY.—Junior House Surgeon. Salary £80 per annum, with board, residence, &c.

SHEFFIELD ROYAL INFIRMARY.—Junior Resident Medical Officer. Salary £60 per annum.

SHOREDITCH AND FINSBURY TUBERCULOSIS DISPENSARY.—Medical Officer. Salary £250 per annum.

SOUTH SHIELDS, INGHAM INFIRMARY AND SOUTH SHIELDS AND WESTOE DISPENSARY.—Senior and Junior House Surgeon. Salary £100 and £90 per annum respectively, with residence, board, and washing.

STAFFORD, COTON HILL LUNATIC HOSPITAL.—Assistant Medical Officer. Salary £125 per annum, with residence, board, and laundry.

TRURO, ROYAL CORNWALL INFIRMARY.—House Surgeon, unmarried. Salary £100 per annum, with rooms, board, and washing.

VICTORIA HOSPITAL FOR CHILDREN, Tite-street, Chelsea, S.W.—House Physician and House Surgeon for six months. Salary £40, with board, lodging, and laundry.

WEST LONDON HOSPITAL, Hammersmith-road, W.—Assistant Anæsthetist.

WINCHESTER, ROYAL HAMPSHIRE COUNTY HOSPITAL.—House Physician. Salary £80 per annum.

WORCESTER GENERAL INFIRMARY.—House Surgeon. Salary £100 per annum, with board, residence, and washing.

THE Chief Inspector of Factories, Home Office, London, S.W., gives notice of vacancies as Certifying Surgeons under the Factory and Workshop Act at Bruton, in the county of Somerset; at Cinderford, in the county of Gloucester; at Kingstown, in the county of Dublin; at Saltcoats, in the county of Ayrshire; and at Stock, in the county of Essex.

Births, Marriages, and Deaths.

BIRTHS.

ANDERSON.—On Dec. 31st, 1911, at Horsmonden, Kent, the wife of F. T. Anderson, M.D., of a son.

LACK.—On Jan. 1st, at Devonshire-place, W., the wife of Dr. Lambert Lack, of a daughter.

MARRIAGES.

GAMBIER—CUTTING.—On Dec. 21st, 1911, at Hastings, Thomas Gambier, M.D., to Ethel Sophia Cutting, B.A., daughter of Arthur Cutting, of Birmingham.

SHIPWAY—BIDDELL.—On Jan. 6th, at Holy Trinity Church, Brompton, Francis Edward Shipway, M.D., to Winifred Adine, elder daughter of William R. Biddell, of Sherwood Oaks, Kenley.

WARREN—JENKINS.—On Jan. 10th, at St. Paul's Church, Ramsgate, by the Rev. G. P. Haydon, uncle of the bridegroom, Richard Warren, F.R.C.S., M.Ch., of 29, Weymouth-street, W., younger son of General Sir Charles Warren, G.C.M.G., J.P., to Violet Irené, eldest daughter of A. C. Jenkins, Esq., of Rose Cottage, Heamoor, Cornwall.

DEATHS.

GAMGEE.—On Jan. 7th, at 45, York-road, Edgbaston, Marion, wife of the late Joseph Sampson Gamgee, of Birmingham, aged 72.

JEX-BLAKE.—On Jan. 7th, at Windydene, Mark Cross, Sussex, Sophia Jex-Blake, M.D., in the 72nd year of her age.

N.B.—A fee of 5s. is charged for the insertion of Notices of Births, Marriages, and Deaths.

Notes, Short Comments, and Answers to Correspondents.

VITAL STATISTICS OF BRITISH GUIANA.

In the report of the Blue-book of British Guiana for the year 1910-1911, received at the Colonial Office last month, it is stated that a census was taken on April 2nd, 1911, when the population was returned at 295,713 souls, exclusive of the aboriginal Indians in the unfrequented portions of the colony. There were 8332 births registered during the year. The birth-rate per 1000 of the estimated population of each of the different races representing the community was in 1910 as follows: Europeans, other than Portuguese, 13·9; Portuguese, 23·2; East Indians, 24·4; Chinese, 35·6; aborigines, 65·1; blacks, 29·7; mixed races, 27·0. With the exception of Europeans, Chinese, and aborigines, which show increases, a decrease has been noted in respect of each race on the figures for 1909. On the figures for 1908 there is an increase as regards each race except Europeans and mixed races, which show slight decreases, and East Indians, which figure remains the same. Of the births registered 3325, or 39·9 per cent., were legitimate and 5007, or 60·1 per cent., illegitimate. The deaths registered were 10,424, or 1057 more than in the previous year, when the deaths were 14 less than in 1903. The death-rate was 34·4 per 1000 of the estimated population, as compared with 30·0 in 1909 and 30·8 in 1908. The mean rate for the previous five years was 30·8. There were 1954 deaths of children under one year of age, or 234 per 1000, the previous year's figures having been 1872, or 209 per 1000. The figures of 1910, however, are lower than in 1907, when they were 2202, or 256 per 1000. The mean rate for the past five years continues at 210 per 1000.

The health of the colony showed no marked improvement over the previous year. There was no epidemic of any dangerous, infectious, or contagious disease, though the existence of yellow fever and plague in neighbouring places gave rise to considerable anxiety. Efforts are being made by legislative and other action to control the mosquito pest. The number of screened vats has been greatly increased. Quinine is sold at all post offices to the general public at cost price; it is also distributed by the sugar estates free to their labourers. Prisoners and members of the police force are supplied by the colony with free quinine. There were 7556 fewer cases of malarial fever treated in the estates' hospitals than in the previous year. The medical department continues to give attention to the question of ankylostomiasis, and the interest that has been aroused in this connexion among the employers of labour on the sugar estates and among the labourers themselves is bearing fruit. The five principal causes of death throughout the colony during the past five years are given by the Registrar-General as follows: Malaria, 20·2 per cent.; pneumonia and bronchitis, 12·7 per cent.; kidney diseases, 12·4 per cent.; diarrhœal diseases, 7·1 per cent.; phthisis and other forms of tuberculosis, 6·0 per cent. The total rainfall for the calendar year 1910 at the Botanic Gardens, Georgetown, was 101·46 inches. The amount of sunshine recorded during the year was 2391 hours. The hospitals and asylums of the colony were maintained during the year in their usual efficient condition. There are five public hospitals in the principal centres of population, and the outlying districts are served by dispensary hospitals and dispensaries. The immigration law also requires the maintenance of hospitals on every plantation on which there are indentured East Indian labourers, and those institutions are available for the treatment of emergency and pauper cases from the general community. There were 655 patients in the public hospitals at the beginning of the year, and 16,331 were admitted during the year. The daily average under treatment was 712. There were 2046 deaths. In addition to those admitted to hospital, outdoor treatment was given to 74,877 persons.

At the Leper Asylum there were 413 patients when the year began—287 males and 126 females—and during the year 121 were admitted. The Lepers Ordinance, 1905, allowed lepers to be isolated in private at their homes instead of being sent to the Leper Asylum when the governor is satisfied that it can be done without danger of infection to other persons. But it is now known that lepers suffering from ulcers are a far more dangerous source of infection than others, and accordingly a new ordinance has been passed, providing that such lepers shall not be isolated in private, but must be sent to the Leper Asylum.

THE PREVENTION OF DISEASE AND THE SAVING OF LIFE BY THE DESTRUCTION OF MOSQUITOES.

We have received from Dr. H. A. Alford Nicholls, C.M.G., Senior Medical Officer of Dominica, an interesting little pamphlet with the above title, intended for public instruction among the people of Dominica and other mosquito-infested districts. It makes no pretence to originality, but it is an unusually clear, concise, and useful statement for the public of what everyone living in such a district should know in relation to the connexion of mosquitoes with disease, the life-history of the three disease-carrying mosquitoes, and the best methods of dealing with them. It is just the kind of pamphlet to be read with the intelligent interest necessary as a stimulant to action. It is printed at the Bulletin Office, Roseau, Dominica, West Indies.

"THE CHEMICAL WORLD."

We have received from Messrs. J. and A. Churchill a copy of the first number of *The Chemical World*. This periodical is to be published in monthly numbers, and judging from the excellent series of articles in the first number we anticipate that it will appeal to a wide *clientèle*, chiefly to those interested in the advances of chemical science and technology. Amongst the interesting articles in the first number are "The Physics and Chemistry of Colloids" (the first of a series), "The Food and Drugs Acts and a Court of Reference," "Notes on Chemical Research," "The Detection of Mydriatic Alkaloids," "The Chemical Characterisation of Soils," "Cellulose and Cellulose Products," and "Chemical Research." The journal is well printed, and its general plan is attractive.

Communications not noticed in our present issue will receive attention in our next.

A DIARY OF CONGRESSES.

We shall publish this diary from time to time that our readers may have under their hands the dates of the approaching scientific Congresses. It is unnecessary to issue the lists of all these functions week by week, and we propose to make only such gatherings as will occur in the immediate future the subject of regular announcement. The following Congresses, Conferences, and Exhibitions are announced for the next few months:—

Jan. 20th–27th (Hong-Kong).—Second Biennial Congress of the Far Eastern Association of Tropical Medicine.
Feb. 13th–14th (London).—Central Poor-Law Conference.
March 7th–11th (Berlin).—Thirty-third Balneological Congress.
March 23rd–April 4th (London, Royal Agricultural Hall).—International Smoke Abatement Exhibition.
" (London).—First Congress of Pure Food and Health Society of Great Britain.
April 1st–7th (Tunis).—Twenty-second Congress of French-speaking Alienists and Neurologists.
" 8th–13th (Rome).—Seventh International Congress of Dermatology and Syphilology.
" 8th–15th (Johannesburg).—Thirteenth South African Medical Congress.
" 14th–20th (Rome).—Seventh International Congress on Tuberculosis.
" 15th–18th (Wiesbaden).—Twenty-ninth German Congress for Internal Medicine.
" (Giessen).—Congress on Study of Families, Inheritance, and Race Hygiene.
Spring (London).—Second Optical Convention.
May 7th–17th (Washington).—Ninth International Red Cross Conference.
" 23rd–25th (Hanover).—Nineteenth Meeting of the Union of German Laryngologists.
" 25th–27th (Paris).—International Musical Festival.
" 27th–June 1st (London).—Eighteenth International Congress of Americanists.
" 29th–31st (Berlin).—Fifteenth Session of the German Society for Gynæcology.
" (London).—International Horticultural Exhibition.

METEOROLOGICAL READINGS.

(Taken daily at 8.30 a.m. by Steward's Instruments.)

THE LANCET Office, Jan. 10th, 1912.

The following journals, magazines, &c., have been received:— Journal of Tropical Medicine and Hygiene, Journal für Psychologie und Neurologie, Therapeutic Gazette, Archives of the Roentgen Ray, St. Bartholomew's Hospital Gazette, Medical Review of Reviews, Encyclopédie Médicale, Prescriber, Die Therapie der Gegenwart, Journal of Laryngology, Rhinology, and Otology, Review of Neurology and Psychiatry, Women's Industrial News.

Medical Diary for the ensuing Week.

SOCIETIES.

ROYAL SOCIETY OF MEDICINE, 15, Cavendish-square, W. (temporary address during building of new house).

TUESDAY.

THERAPEUTICAL AND PHARMACOLOGICAL SECTION (Hon. Secretaries—H. Charles Cameron, H. H. Dale): at 4.30 P.M.

Paper:
Dr. W. Bain: The Causes and Treatment of High Blood Pressure.

PATHOLOGICAL SECTION (Hon. Secretaries—J. C. G. Ledingham, A. E. Boycott): at 8.30 P.M.
Dr. J. Turner: Two Cases of Amaurotic Idiocy.
Dr. J. A. Braxton Hicks: An Unusual Organism (M. zymogenes) in a Case of Malignant Endocarditis.
Dr. J. C. G. Ledingham: Phagocytosis from the Adsorption Point of View.

THURSDAY.

DERMATOLOGICAL SECTION (Hon. Secretaries—J. H. Sequeira, Wilfrid Fox), at 11, Chandos-street, W.: at 5 P.M.

Cases:
Dr. Parkes Weber; Sequel to Case of Chronic Artificial Skin Eruption (shown Dec. 15th, 1910).
Dr. Sequeira: Cultures of Tricophyton Plicatile obtained by Dr. Sabouraud from Dr. Sequeira's Case of Ringworm with Granulomata.

NEUROLOGICAL SECTION (Hon. Secretaries—Wilfred Harris, T. Grainger Stewart): at 8.30 P.M.

Papers:
Dr. Howard Tooth and Dr. Hinds Howell: Case of Tabetic Amyotrophy with Pathological Report.
Dr. F. E. Batten: Case of Dermato-Myositis with Pathological Examination.
Dr. Wilfred Harris: Two Cases of Hæmato-rhachis.

FRIDAY.

OTOLOGICAL SECTION (Hon. Secretaries—Sydney Scott, A. Logan Turner), at 11, Chandos-street, W.: at 5 P.M.

Discussion:
Factors which Conduce to Success in the Treatment of Otogenic Brain Abscess (opened by Sir Victor Horsley, F.R.S., and Mr. C. E. West).

Demonstration of Cases and Specimens by other Members.

(The Council of the Section will welcome the presentation not only of patients who have been successfully treated for Otogenic Brain Abscess but also of pathological material bearing on the subject under discussion.)

Members of the NEUROLOGICAL and SURGICAL SECTIONS are specially invited to be present and to take part in the discussion.

ELECTRO-THERAPEUTICAL SECTION (Hon. Secretaries—G. Harrison Orton, Cecil R. C. Lyster): at 8.30 P.M.

Paper:
Dr. C. J. Morton: X-Ray Prognosis.

Demonstration:
Dr. James C. Case: X-Ray Stereo Reductions of Bismuth Meals.

MEDICO-LEGAL SOCIETY, 11, Chandos-street, Cavendish-square, W.
TUESDAY.—8.30 P.M., Dr. R. R. Rentoul: Sterilisation of the Unfit.

CHELSEA CLINICAL SOCIETY, St. George's Hospital Medical School, S.W.
TUESDAY.—8.30 P.M., Mr. F. D. Mortimer: Preparation for Anæsthesia.—Mr. A. F. Penny: The Importance of Early Diagnosis and Treatment in Acute Inflammatory Diseases of the Middle Ear.

LONDON DERMATOLOGICAL SOCIETY, 48, Leicester-square, W.C.
TUESDAY.—4.30 P.M., Meeting.

ROYAL METEOROLOGICAL SOCIETY, Institution of Civil Engineers, Great George-street, Westminster, S.W.
WEDNESDAY.—7.45 P.M., Annual General Meeting. Election of Council for 1912. Presentation of the Symons Gold Medal to Prof. C. Abbe. Dr. H. N. Dickson: Some Meteorological Observations.

ROYAL MICROSCOPICAL SOCIETY, 20, Hanover-square, W.
WEDNESDAY.—8 P.M., Annual Address:—The President (Mr. H. G. Plimmer): On Certain Blood Parasites.

LECTURES, ADDRESSES, DEMONSTRATIONS, &c.

MEDICAL GRADUATES' COLLEGE AND POLYCLINIC, 22, Chenies-street, W.C.
MONDAY.—4 P.M., Dr. G. Little: Clinique (Skin). 5.15 P.M. Lecture:—Mr. M. Little: A New Material for Surgical Appliances (with demonstration).
TUESDAY.—4 P.M., Dr. G. A. Sutherland: Clinique (Medical). 5.15 P.M., Lecture:—Mr. W. Stuart-Low: Nasal Catarrh.
WEDNESDAY.—4 P.M., Mr. C. Rowntree: Clinique (Surgical). 5.15 P.M., Lecture:—Dr. G. Pernet: Animal Parasites.
THURSDAY.—4 P.M., Dr. N. Pitt: Clinique (Medical). 5.15 P.M., Lecture:—Mr. A. McNab: Glaucoma.
FRIDAY.—4 P.M., Mr. E. A. Peters: Clinique (Ear, Nose, and Throat).

POST-GRADUATE COLLEGE, West London Hospital, Hammersmith-road, W.
MONDAY.—10 A.M., Dr. Simson: Diseases of Women. 10.30 A.M., Surgical Registrar: Demonstration of Cases in Wards. 12 noon, Dr. Bernstein: Pathological Demonstration. 2 P.M., Medical and Surgical Clinics. X Rays. Operations. 2.30 P.M., Mr. Dunn: Diseases of the Eye. 5 P.M., Lecture:—Mr. Bidwell: Surgical Treatment of Floating Kidney.
TUESDAY.—10 A.M., Dr. Robinson: Gynæcological Operations. 11.30 A.M., Mr. Etherington-Smith: Demonstration of Minor Operations. 2 P.M., Medical and Surgical Clinics. X Rays. Operations. Dr. Davis: Diseases of the Throat, Nose, and Ear. 2.30 P.M., Dr. Abraham: Diseases of the Skin. 5 P.M., Lecture:—Dr. Davis: Diseases of the Throat. (Lecture II.)
WEDNESDAY.—10 A.M., Dr. Saunders: Diseases of Children. Dr. Davis: Operations of the Throat, Nose, and Ear. 10.30 A.M., Surgical Registrar: Demonstration of Cases in Wards. 2 P.M., Medical and Surgical Clinics. X Rays. Operations. Mr. B. Harman: Diseases of the Eye. 2.30 P.M., Dr. Simson: Diseases of Women. 5 P.M., Lecture:—Dr. Beddard: Practical Medicine. (Lecture I.)
THURSDAY.—10 A.M., Dr. Simson: Gynæcological Demonstration. 12.15 P.M., Lecture:—Dr. G. Stewart: Practical Medicine. 2 P.M., Medical and Surgical Clinics. X Rays. Operations. 2.30 P.M., Mr. Dunn: Diseases of the Eye. 5 P.M., Lecture:—Mr. Baldwin: Practical Surgery. (Lecture I.)
FRIDAY.—10 A.M., Dr. Robinson: Gynæcological Operations. 2 P.M., Medical and Surgical Clinics. X Rays. Operations. Dr. Davis: Diseases of the Throat, Nose, and Ear. 2.30 P.M., Dr. Abraham: Diseases of the Skin. 5 P.M., Lecture:—Dr. Saunders: Clinical (with cases).
SATURDAY.—10 A.M., Dr. Saunders: Diseases of Children. Dr. Davis: Operations of the Throat, Nose, and Ear. Mr. Bishop Harman: Diseases of the Eye. 10.30 A.M., Medical Registrar: Demonstration of Cases in Wards. 2 P.M., Medical and Surgical Clinics. X Rays. Operations.

NORTH-EAST LONDON POST-GRADUATE COLLEGE, Prince of Wales's General Hospital, Tottenham, N.
MONDAY.—Clinics:—10.30 A.M., Surgical Out-patient (Mr. B. Gillespie). 2.30 P.M., Medical Out-patient (Dr. T. R. Whipham): Nose, Throat, and Ear (Mr. H. D. Gillies). 3 P.M., Clinical Pathology and Pathological Demonstration (Dr. W. H. Duncan).
TUESDAY.—Clinic: 2.30 P.M., Operations. Clinics:—Medical Out-patient (Dr. A. G. Auld).; Surgical (Mr. Howell Evans); Gynæcological (Dr. A. B. Giles). 3.30 P.M., Medical In-patient (Dr. A. J. Whiting). 4.30 P.M., Lecture:—Dr. A. G. Auld; The Value of X Rays in the Diagnosis of Chest Affections.
WEDNESDAY.—Clinics:—2 P.M., Throat Operations (Mr. Gillies). 2.30 P.M., Children's Out-patient (Dr. T. R. Whipham); Skin (Dr. G. N. Meachen); Eye (Mr. R. P. Brooks). 3 P.M., X Rays (Mr. W. Steuart); Clinical Pathology and Pathological Demonstration (Dr. W. H. Duncan). 5.30 P.M., Eye Operations (Mr. Brooks). 4.30 P.M., Lecture:—Mr. W. Stewart: The Therapeutic Uses of X Rays.
THURSDAY.—2.30 P.M., Gynæcological Operations (Dr. A. B. Giles). Clinics:—Medical Out-patient (Dr. A. J. Whiting); Surgical (Mr. Carson). 3 P.M., Medical In-patient (Dr. G. P. Chappel).
FRIDAY.—2.30 P.M., Operations. Clinics:—Medical Out-patient (Dr. A. G. Auld); Surgical (Mr. B. Gillespie); Eye (Mr. R. P. Brooks). 3 P.M., Medical In-patient (Dr. R. M. Leslie); Clinical Pathology and Pathological Demonstration (Dr. W. H. Duncan).

LONDON SCHOOL OF CLINICAL MEDICINE, Dreadnought Hospital, Greenwich.
MONDAY.—2 P.M., Operations. 2.15 P.M., Mr. Turner: Surgery. 3.15 P.M., Sir Dyce Duckworth: Medicine. 4.30 P.M., Mr. R. Lake: Ear and Throat. Out-patient Demonstrations:—10 A.M., Surgical and Medical. 12 noon, Ear and Throat. 3.15 P.M., Special Lecture:—Sir Dyce Duckworth: Rheumatic Fever.
TUESDAY.—2 P.M., Operations. 3.15 P.M., Dr. R. Wells: Medicine. 2.15 P.M., Mr. R. Carling: Surgery. 4.15 P.M., Sir M. Morris: Diseases of the Skin. Out-patient Demonstrations:—10 A.M., Surgical and Medical. 12 noon, Skin. 4.30 P.M., Special Lecture:—Mr. Walton: Diagnosis of Peripheral Nerve Lesions.
WEDNESDAY.—2 P.M., Operations. 2.15 P.M., Dr. F. Taylor: Medicine. 3.30 P.M., Mr. Cargill: Ophthalmology. Out-patient Demonstrations:—10 A.M., Surgical and Medical. 11 A.M., Eye. 5 P.M., Special Demonstration (or Lecture):—Mr. McGavin: Surgical.
THURSDAY.—2 P.M., Operations. 2.15 P.M., Dr. G. Rankin: Medicine. 3.15 P.M., Sir W. Bennett: Surgery. Out-patient Demonstrations:—10 A.M., Surgical and Medical. 12 noon, Ear and Throat. 4.30 P.M., Special Lecture:—Dr. Gandy: Anæsthetics.
FRIDAY.—2 P.M., Operations. 2.15 P.M., Sir J. Rose Bradford: Medicine. 3.15 P.M., Mr. McGavin: Surgery. Out-patient Demonstrations:—10 A.M., Surgical and Medical. 12 noon, Skin.
SATURDAY.—10 A.M., Radiography. 11 A.M., Dr. A. Davies: Pathological Demonstration. 2 P.M., Operations. Out-patient Demonstration:—10 A.M., Surgical and Medical. 11 A.M., Eye.

HOSPITAL FOR SICK CHILDREN, Great Ormond-street, W.C.
THURSDAY.—4 P.M., Lecture:—Mr. E. M. Corner: Delayed Chloroform Poisoning.

ST. JOHN'S HOSPITAL FOR DISEASES OF THE SKIN, 49, Leicester-square, W.C.
TUESDAY.—6 P.M., Dr. W. Griffith: Pathology of the Skin Appendages.
THURSDAY.—6 P.M., Chesterfield Lecture:—Dr. M. Dockrell: Acne Vulgaris in its Three Stages—I., Comedo; II., Indurata; III., Necrotica.

ROYAL INSTITUTION OF GREAT BRITAIN, Albemarle-street, Piccadilly, W.
TUESDAY.—3 P.M., Prof. W. Bateson: The Study of Genetics. (Lecture I.)
FRIDAY.—9 P.M., Prof. Sir James Dewar: Heat Problems.

ROYAL SANITARY INSTITUTE, 90, Buckingham Palace-road, S.W.
MONDAY.—7.30 P.M., Prof. H. R. Kenwood: Fresh Air (illustrated by lantern slides).
FRIDAY.—4 P.M., Dr. T. D. Lister: Problem of After-care of Sanatoria Patients.

ANCOATS HOSPITAL, Manchester.
THURSDAY.—4.15 P.M., Dr. E. B. Leech: Difficulties in the Diagnosis between Diseases of the Chest and Abdomen. (Post-Graduate Clinic.)

MANCHESTER ROYAL INFIRMARY.
MONDAY.—4.30 P.M., Dr. A. T. Wilkinson: Demonstration of Medical Cases.
FRIDAY.—4.30 P.M., Mr. W. Thorburn: Neuralgia and its Surgical Treatment.

OPERATIONS.

METROPOLITAN HOSPITALS.

MONDAY (15th).—London (2 P.M.), St. Bartholomew's (1.30 P.M.), St. Thomas's (3.30 P.M.), St. George's (2 P.M.), St. Mary's (2.30 P.M.), Middlesex (1.30 P.M.), Westminster (2 P.M.), Chelsea (2 P.M.), Samaritan (Gynæcological, by Physicians, 2 P.M.), Soho-square (2 P.M.), Gt. Northern Central (2.30 P.M.), West London (2.30 P.M.), London Throat (9.30 A.M.), Royal Free (2 P.M.), Guy's (1.30 P.M.), Children, Gt. Ormond-street (9 A.M.), St. Mark's (2.30 P.M.), Central London Throat and Ear (Minor 9 A.M., Major 2 P.M.).

TUESDAY (16th).—London (2 P.M.), St. Bartholomew's (1.30 P.M.), St. Thomas's (3.30 P.M.), Guy's (1.30 P.M.), Middlesex (1.30 P.M.), Westminster (2 P.M.), West London, (2.30 P.M.), University College (2 P.M.), St. George's (1 P.M.), St. Mary's (1 P.M.), St. Mark's (2.30 P.M.), Cancer (2 P.M.), Metropolitan (2.30 P.M.), London Throat (3.30 A.M.), Samaritan (9.30 A.M. and 2.30 P.M.), Throat, Golden-square (9.30 A.M.), Soho-square (2 P.M.), Chelsea (2 P.M.), Children, Gt. Ormond-street (9 A.M. and 2 P.M., Ophthalmic, 2 P.M.), Tottenham (2.30 P.M.). Central London Throat and Ear (Minor, 9 A.M., Major, 2 P.M.), Royal National Orthopædic (9.30 A.M. and 4 P.M.).

WEDNESDAY (17th).—St. Bartholomew's (1.30 P.M.), University College (2 P.M.), Royal Free (2 P.M.), Middlesex (1.30 P.M.), Charing Cross (3 P.M.), St. Thomas's 2 P.M.), London (2 P.M.), King's College (2 P.M.), St. George's (Ophthalmic, 1 P.M.), St. Mary's (2 P.M.), St. Peter's (2 P.M.), Samaritan (9.30 A.M. and 2.30 P.M.), Gt. Northern Central (2.30 P.M.), Westminster (2 P.M.), Metropolitan (2.30 P.M.), London Throat (9.30 A.M.), Cancer (2 P.M.), Throat, Golden-square (9.30 A.M.), Guy's (1.30 P.M.), Royal Ear (2 P.M.), Children, Gt. Ormond-street (9 A.M. and 9.30 A.M., Dental, 2 P.M.), Tottenham (Ophthalmic, 2.30 P.M.), West London (2.30 P.M.), Central London Throat and Ear (Minor, 9 A.M., Major, 2 P.M.).

THURSDAY (18th).—St. Bartholomew's (1.30 P.M.), St. Thomas's (3.30 P.M.), University College (2 P.M.), Charing Cross (3 P.M.), St. George's (1 P.M.), London (2 P.M.), King's College (2 P.M.), Middlesex (1.30 P.M.), St. Mary's (2.30 P.M.), Soho-square (2 P.M.), North-West London (2 P.M.), Gt. Northern Central (Gynæcological, 2.30 P.M.), Metropolitan (2.30 P.M.), London Throat (9.30 A.M.), Samaritan (9.30 A.M and 2.30 P.M.), Throat, Golden-square (9.30 A.M.), Guy's (1.30 P.M.), Royal National Orthopædic (9 A.M. and 3.30 P.M.), Royal Ear (2 P.M.), Children Gt. Ormond-street (9 A.M. and 2 P.M.), Tottenham (Gynæcological, 2.30 P.M.), West London (2.30 P.M), Central London Throat and Ear (Minor, 9 A.M., Major, 2 P.M.).

FRIDAY (19th).—London (2 P.M.), St. Bartholomew's (1.30 P.M.), St. Thomas's (3.30 P.M.), Guy's (1.30 P.M.), Middlesex (1.30 P.M.), Charing Cross (3 P.M.), St. George's (1 P.M.), King's College (2 P.M.), St. Mary's (2 P.M.), Ophthalmic (10 A.M.), Cancer (2 P.M.), Chelsea (2 P.M.), Gt. Northern Central (2.30 P.M.), West London (2.30 P.M.), London Throat (9.30 A.M.), Samaritan (9.30 A.M. and 2.30 P.M.), Throat, Golden-square (9.30 A.M.), Royal National Orthopædic (3.30 P.M.), Soho-square (2 P.M.), Children, Gt. Ormond-street (9 A.M., Aural, 2 P.M.), Tottenham (2.30 P.M.), St. Peter's (2 P.M.)., Central London Throat and Ear (Minor, 9 A.M., Major, 2 P.M.).

SATURDAY (20th).—Royal Free (9A.M.), London (2 P.M.), Middlesex (1.30 P.M.), St. Thomas's (2 P.M.), University College (9.15 A.M.), Charing Cross (2 P.M.), St. George's (1 P.M.), St. Mary's (10 A.M.), Throat, Golden-square (9.30 A.M.), Guy's (1.30 P.M.), Children, Gt. Ormond-street (9 A.M. and 9.30 A.M.), West London (2.30 P.M.).

At the Royal Eye Hospital (2 P.M.), the Royal London Ophthalmic (10 A.M.), the Royal Westminster Ophthalmic (1.30 P.M.), and the Central London Ophthalmic (2 P.M.), Hospital operations are performed daily.

EDITORIAL NOTICES.

IT is most important that communications relating to the Editorial business of THE LANCET should be addressed *exclusively* "TO THE EDITOR," and not in any case to any gentleman who may be supposed to be connected with the Editorial staff. It is urgently necessary that attention should be given to this notice.

It is especially requested that early intelligence of local events having a medical interest, or which it is desirable to bring under the notice of the profession, may be sent direct to this office.

Lectures, original articles, and reports should be written on one side of the paper only, AND WHEN ACCOMPANIED BY BLOCKS IT IS REQUESTED THAT THE NAME OF THE AUTHOR, AND IF POSSIBLE OF THE ARTICLE, SHOULD BE WRITTEN ON THE BLOCKS TO FACILITATE IDENTIFICATION.

Letters, whether intended for insertion or for private information, must be authenticated by the names and addresses of their writers—not necessarily for publication.

We cannot prescribe or recommend practitioners.

Local papers containing reports or news paragraphs should be marked and addressed "To the Sub-Editor."

Letters relating to the publication, sale and advertising departments of THE LANCET *should be addressed "To the Manager."*

We cannot undertake to return MSS. not used.

MANAGER'S NOTICES.

THE INDEX TO THE LANCET.

The Index and Title-page to Vol. II. of 1911 were given in THE LANCET of Dec. 30th, 1911.

VOLUMES AND CASES.

VOLUMES for the second half of the year 1911 are now ready. Bound in cloth, gilt lettered, price 16*s.*, carriage extra.

Cases for binding the half-year's numbers are also ready. Cloth, gilt lettered, price 2*s.*, by post 2*s.* 3*d.*

To be obtained on application to the Manager, accompanied by remittance.

TO SUBSCRIBERS.

WILL Subscribers please note that only those subscriptions which are sent direct to the Proprietors of THE LANCET at their Offices, 423, Strand, London, W.C., are dealt with by them? Subscriptions paid to London or to local newsagents (with none of whom have the Proprietors any connexion whatever) do not reach THE LANCET Offices, and consequently inquiries concerning missing copies, &c., should be sent to the Agent to whom the subscription is paid, and *not* to THE LANCET Offices.

Subscribers, by sending their subscriptions direct to THE LANCET Offices, will insure regularity in the despatch of their Journals and an earlier delivery than the majority of Agents are able to effect.

THE COLONIAL AND FOREIGN EDITION (printed on thin paper) is published in time to catch the weekly Friday mails to all parts of the world.

The rates of subscriptions, post free from THE LANCET Offices, have been reduced, and are now as follows:—

FOR THE UNITED KINGDOM.		TO THE COLONIES AND ABROAD.	
One Year	£1 1 0	One Year	£1 5 0
Six Months	0 12 6	Six Months	0 14 0
Three Months	0 6 6	Three Months	0 7 0

(The rate for the United Kingdom will apply also to Medical Subordinates in India whose rates of pay, including allowances, is less than Rs.50 per month.)

Subscriptions (which may commence at any time) are payable in advance. Cheques and Post Office Orders (crossed "London County and Westminster Bank, Covent Garden Branch") should be made payable to the Manager, Mr. CHARLES GOOD, THE LANCET Offices, 423, Strand, London, W.C.

TO COLONIAL AND FOREIGN SUBSCRIBERS.

SUBSCRIBERS ABROAD ARE PARTICULARLY REQUESTED TO NOTE THE RATES OF SUBSCRIPTIONS GIVEN ABOVE.

The Manager will be pleased to forward copies direct from the Offices to places abroad at the above rates, whatever be the weight of any of the copies so supplied.

SOLE AGENTS FOR AMERICA—Messrs. WILLIAM WOOD AND CO., 51, Fifth Avenue, New York, U.S.A.

Communications, Letters, &c., have been received from—

A.—Ardath Tobacco Co., Lond.; After-Care Association, Lond., Secretary of; Mr. E. Arnold, Lond.; Messrs. C. Ash and Co., Lond.; Messrs. Allen and Hanburys, Lond.; Automobile Association, Lond.; Dr. J. C. Dalmahoy Allan, Hong-Kong; Mr. A. A.; A. L. H.; Mr. Sidney J. Arkwright, Wickham Market.

B.—Messrs. Blundell and Rigby, Lond.; Mr. E. W. Blasius, Lond.; Birmingham and Midland Eye Hospital, Secretary of; Colonel S. H. Browne, I.M.S., Cannes; Mr. A. A. Bradburne, Manchester; Bovril, Ltd., Lond.; Captain J. Hay Burgess, I.M.S., Madras; Mr. F. A. Brockhaus, Lond.; Dr. E. M. Brown, Washington, U.S.A.; Birmingham General Hospital, Secretary of; Mr. W. An Address
ON
EXAMPLES OF THE RESOURCES OF SURGERY IN CERTAIN EMERGENCIES.[1]

BY CHARLES A. BALLANCE, M.V.O., M.S. LOND., F.R.C.S. ENG.,
SURGEON TO ST. THOMAS'S HOSPITAL, ETC.

MR. PRESIDENT AND GENTLEMEN,—The Hunterian is one of our oldest medical societies, and as Hunter was a London surgeon it seems in the fitness of things that surgery should occupy a prominent place in your yearly programme. The society was founded in 1819, and its first President was Sir William Blizzard, a man evidently of remarkable energy and ability. He was elected President when 76 years old, at 84 he successfully amputated a thigh, at 91 he was himself operated upon for cataract, and a few hours after the operation was bled to 8 oz. In these days most members of our profession who survive to old age, unlike Sir William Blizzard, may echo the lament of the Psalmist, "Collocavit me in obscuris sicut mortuos saeculi."

SOME OBSERVATIONS ON MEDICAL SOCIETIES.

At the jubilee of the society in 1869 an address was given by Henry Fotherby, in which is well described the evolution of the societies of men from the earliest times, and in which the history of the Hunterian Society to that date is given in considerable detail. In that address Fotherby remarked:—

> The success of the society has been *felt* in the experiences of its members, rather than *written* in the minutes of its proceedings. Nothing in the shape of a party or clique has ever been known among its members. May this happy state long continue.

Some common bond of interest is essential to the life of a society: Ratio societatis vinculum. Instinct led the barbarian to unite with his fellow for the mere purpose of support and defence.

> These ends being secured, the religious idea, as innate to humanity, appears to be the next cause of association; and very early do we find a class, society, or caste set apart for the culture of religion, as the Druids, the Augurs, and the Levites. With them dwelt the influence and authority which wisdom and learning ever exercise over ignorance; and to them, in virtue of their supposed influence with the gods, was committed equally the care of souls and bodies and the formation of laws. In the classic systems of Greece and Rome this union of priest and physician was discontinued from the period of the Esculapian institutions, but with the Gothic and other nations it was long maintained.

The Royal Society, founded in 1645, is the oldest of our scientific societies. As an off-shoot from it came the Mathematical Society, founded in 1717; this society existed independently for more than a century, and ended by becoming merged in the Astronomical Society in 1845.

The oldest of our purely medical societies is the Medical Society of London, founded in 1773, and still happily in vigorous and independent existence. Next came a Society for the Improvement of Medical and Chirurgical Knowledge, founded by John Hunter himself, in 1783, which had but a short life. The Royal Medical and Chirurgical Society was founded in 1805.

Two important non-medical scientific societies—viz., the London Institution and the Geological Society—were founded in 1807. Your own society, the Hunterian, was founded in 1819, and after it came the Pathological Society of London, founded in 1846, and numerous other medical societies, most of which are now merged in the Royal Society of Medicine.

THE NATIONAL INSURANCE ACT.

In recent years medical men have had to return to the primitive instinct and form societies, such as the Medical Defence Union, for the mere purpose of mutual support and defence; it is noteworthy that this has been the *last*, and not the first, motive for their association.

A fresh phase in this process is with us now. The British Government has passed a Bill through Parliament which professes to provide *adequate medical attendance* for 15,000,000 people. All medical men know that "adequate medical attendance" for the poor is not provided for by this Act, and that it cannot be so provided unless the Act is amended so as to place the medical service under medical control, which alone can make it a success.

The Act perpetuates by Government sanction the abominable slavery of medical treatment controlled by laymen, and if it is worked as it stands, will fasten the hateful yoke of cheap contract practice on the necks of thousands of medical men, and will reduce numbers of them and their families to penury.

Medical attendance on the poor, as Government service, should receive a fair remuneration like other departments of the Civil Service. There is nothing in the Act about *adequate medical remuneration*. It would be interesting to observe the effect on the legal profession of an Act which would reduce the remuneration of solicitors to a capitation fee of 4*s*. 6*d*. per annum. The leaders of the British Medical Association have invented a new definition of the word "*cardinal*" which is not understood by the rank and file of the profession.

If a government becomes responsible for the medical care of the poor such government care ought to reach a standard approximately like that within the reach of the rich. This the Act does not do. The medical aspect of the problem is purely medical, and any attempt at lay control and inspection of *medical treatment* or benefit is a gigantic fraud on the people, and an intolerable oppression of those engaged in the most self-sacrificing of all callings.

THE ORIGIN OF CANCER.

Fotherby on the occasion to which I have alluded said:—

> There are indications that we may be already on the threshold of grand discoveries which will be equivalent in the field of medicine to those of Newton in physics, by which we may not only recognise the secondary causes of diseases, but deduce the general laws which under these become active, and their correlation with the conditions and laws of health.

Anæsthetics were already discovered, but the work of Pasteur and of Lister was yet to come. We have seen that work and in it the fulfilment of Fotherby's forecast, for its importance to surgery is not less than that of Newton's work to physics.

We are now looking forward to further discoveries, as were the men of Fotherby's time—notably the solution of the cancer problem. You will all have listened to or read the lectures of surpassing interest on cancer recently delivered by a great surgeon and pathologist of our own day; the conclusion arrived at was that the problem was insoluble, for he said:—

> There is one, and only one, explanation of the conduct of the cancer cell—that it has been endowed with that wondrous gift which no man has seen and which no man can understand—the gift of life; and that, owing to that gift, it has become an independent creature, a new creation of living thing. The host in which it dwells has fashioned it out of his own tissues and in the likeness of his tissues, and, to borrow the figurative language of Scripture, the Creator has breathed into it the breath of life, and it becomes a veritable Frankenstein's monster, bent on the destruction of its host. After ages of past and present civilisation, during which searchers and philosophers have sought to explain the origin and nature of life, we have come no further than this, and he who discovers the true origin of cancer will have solved the enigma which has hitherto baffled the searchers and philosophers in all ages and of all countries.[2]

Surely it is true that the normal squamous cell, no less than the carcinomatous squamous cell, has had breathed into it by the Creator the breath of life. Surely the discovery of the intimate nature of tubercle, malaria, Mediterranean fever, tetanus, and other infective diseases did not solve the origin of life, and we may hope that the intimate nature of cancer and its treatment will be discovered without the workers in this field of science being oppressed by the tremendous problem which Sir Henry Butlin supposes must confront them.

No one has given any more satisfying explanation of the origin of life than that found in the Scripture—

> Thou, Lord, in the beginning hast laid the foundation of the earth: and the Heavens are the work of Thy hand.

All who labour to solve the problems of Nature may say with the Psalmist—

> I muse upon all Thy works, yea, I exercise myself in the works of Thy hands.

Hunter was a pathologist, even more than a surgeon, perhaps because the resources of surgery were in his day so limited. He certainly looked to pathology as the foundation for any new departure in surgical practice. In one of his earliest works there occurs a passage which I cannot but

[1] The Oration in Surgery delivered before the Hunterian Society, Jan. 10th 1912.

[2] THE LANCET, Dec. 2nd, 1911, p. 1539.

contrast with that which I have quoted from Sir Henry Butlin:—

> By persisting in this method of reasoning and attributing everything we are unable to explain to Divine intervention, we block up the gateway and stop up the sources through which come all that adorns life, promotes the arts, and increases the energy and capacity of the human mind. Who has explained the nature of the human body? Who has looked the phenomena of Nature through and through? No one. Many matters lie hidden in obscurity, from which they will not be dragged out without great labour, the united endeavours of many men, and the lapse of a considerable time.

HUNTER'S WORK ON POPLITEAL ANEURYSM.

In Hunter's works—especially in his writings on Inflammation and the Blood—we find clear evidence of his strenuous efforts to elucidate the problems of pathology. From the point of view of surgery, Hunter's name will ever be associated with the cure of popliteal aneurysm by ligation of the femoral artery. In the time of Hunter the only successful treatment of popliteal aneurysm was amputation; the old operation for the aneurysm when applied to the popliteal artery always ended in gangrene and death.

Into this tangle of hæmorrhage, gangrene, and death the genius of Hunter broke with resounding advantage. Notwithstanding the belief of his colleagues at St. George's that the artery was so diseased above the aneurysm that it could not be tied in continuity he affirmed that it was not—his argument was in fact this: if the artery can be successfully tied after amputation, why not tie the artery in continuity where it would be tied in amputation, and thus both save the limb and cure the aneurysm?

TREATMENT OF SURGICAL EMERGENCIES A CENTURY AGO.

A surgeon of to-day looking over the works of Hunter, or his immediate successors, cannot fail to be struck with the small place that surgical intervention then held in the treatment of emergencies. Even 30 years ago the risk attending surgical operations was so considerable that they were delayed as long as possible, whereas now so little is the risk and discomfort attending most operations that surgical intervention has become the method of choice for those affections amenable thereto.

In Hunter's time few conditions were considered as surgical emergencies—that is, as requiring an immediate surgical operation. External hæmorrhage, retention of urine, mechanical obstruction to respiration in the upper air-passages, and obviously depressed fracture of the skull would perhaps complete the list. When an injury to a limb required operation amputation was almost always resorted to; injured viscera were considered beyond surgical aid. Strangulated hernia was mostly treated by futile and dangerous expedients. So limited were the resources of surgery 100 years ago to deal with the lethal consequences of acute disease and injury that the contrast with the present time is amazing.

SOME EXAMPLES OF ABDOMINAL EMERGENCIES: INTESTINAL OBSTRUCTION.

Let us first take, for example, some of the emergencies of abdominal surgery. So recent is our knowledge of the proper treatment of intestinal obstruction that I myself remember the first case in which a median incision was made at St. Thomas's Hospital to discover the site of obstruction before the intestine was opened, the universal practice hitherto having been blindly to perform left lumbar colotomy, which, of course, in many cases was entirely useless.

Cases of acute obstruction are always with us.

CASE 1.—Some years ago a woman, aged 45 years, came under my care with an umbilical hernia of the size of a cocoanut. She had been vomiting, and had had acute pain for four days. Several attempts had been made to reduce the hernia by taxis. When I saw her she was very ill, and the odour that permeated the skin made it obvious that the intestine in the hernia was gangrenous. At the operation 12 feet of ashy grey and black, gangrenous small intestine were exposed, of which 6 feet had been returned by the taxis into the abdominal cavity. The gangrenous mass was cut away 6 inches on each side of the limit of dead tissue, through apparently healthy intestinal wall. The ends were brought out through the wound, and the patient was infused and stimulated. I intended to perform an anastomosis directly the condition of the patient justified the measure. She lived five days, but never rallied sufficiently for a second operation to be attempted. Food was ejected through the proximal opening in the bowel almost as soon as it was swallowed; the only nourishment that was retained for any length of time was a mixture of chopped oysters and cream.

At the post-mortem examination it was found that the proximal opening was only 12 inches from the distal end of the duodenum, and that both ends of the intestine were gangrenous for 2 inches from the line of section. It was, therefore, clear that at the operation I had not gauged correctly the full extent of the gangrenous process. This case is a good example of the danger attending the prolonged use of taxis.

CASE 2.—Again, a man, aged 30 years, of considerable muscular development, was admitted into St. Thomas's Hospital under my care about 20 years ago in a pulseless condition, with a right strangulated scrotal hernia. He had been in severe pain for five days and had been constantly vomiting. When he was brought to the theatre no pulse could be detected in the carotids, and only a feeble flicker could be heard over the heart with the stethoscope. No anæsthetic was necessary, the man seemed like one already dead. While I dealt with the hernia, a vein was opened in the arm and saline solution and brandy infused; the proportion of brandy used was one ounce to one pint of saline solution. By the time eight pints of this mixture had been slowly infused the pulse was full and bounding in all the arteries, and the man no longer seemed dead, but was so drunk and obstreperous that five men were required to hold him down.

Another instructive illustration of obstruction is the following:—

CASE 3.—A man, aged 21 years, was admitted to St. Thomas's Hospital two months ago. He had had very acute pain and vomiting for 36 hours and had previously for a long time suffered from what was called indigestion. The abdomen below the umbilicus was very much distended, there was shifting dulness in the flanks, and the liver dulness had disappeared. At the operation an acute volvulus of the last 2 feet of the ileum was discovered. This was extremely distended, black, and gangrenous. The distended gangrenous volvulus had forced the rest of the small intestine, which was bright red in colour, into the upper part of the abdomen, hence the obliteration of the liver dulness. The man seemed to be doing well for 26 hours, and then failed rapidly and died two days after the operation.

It is to be noted that an acute volvulus seen early may be suspected from the local distension it produces, and that it is amenable to immediate surgical intervention.

PERITONEAL INFECTION.

Again, think how recent is our knowledge of the rational treatment of abdominal disease and injury. Two thousand years ago Celsus wrote:—

> Whenever there is an injury from which survival is possible the immediate indications are two: to see that neither profuse hæmorrhage nor inflammation terminates life.

These indications are still true, but the means of preventing inflammation are a quite recent acquisition. We may now add that the signs which should lead us to diagnose a grave intra-abdominal injury, and therefore to operate, *are not, and they ought never to be, the signs of peritonitis.* Acute abdominal infections are all preceded by a stage in which the disease is purely local and can be ablated or rendered harmless by a simple operation.

Cases of peritoneal infection are now amenable to prompt operation as the following cases show. Similar instances could no doubt be related from the experience of anyone in active practice.

CASE 4.—A carman, aged 20 years, was admitted three days after having been taken ill with pain in the abdomen, vomiting, fever, and constipation. On admission the abdomen was slightly distended, rigid, tender, and motionless on respiration. Temperature 101° F., respirations 40, pulse 120. No tumour felt through the abdominal wall or per rectum; shifting dulness in the right flank. Immediate operation through the right rectus. The abdominal cavity was full of thin pus and all the intestines were bright red. The appendix was gangrenous and was removed. The pus was sponged away from all parts of the abdomen and drainage provided for. Saline solution was infused into the veins and pituitary extract injected hypodermically. On being put back to bed he was propped up and continuous saline infusion per rectum arranged for. Pain was relieved by omnopon and 30 c.c. of anti-colon bacillus serum administered. The patient made good recovery.

CASE 5.—Again, a soldier, aged 37 years, was admitted with a nine months' history of indigestion and a 17 hours' history of acute illness, which commenced with acute pain in the epigastrium. He had vomited, was breathing with difficulty, and was thirsty. The tongue was foul and the pulse quick. The abdomen was full, tender, and scarcely moved at all with respiration. No tumour was felt, the liver dulness had disappeared, and there was shifting dulness in the right flank.

Operation.—On incising the abdominal wall a great quantity of greenish fluid, gas, and stomach contents escaped. A hole of the size of a threepenny-piece was found in the stomach wall near the pylorus. The opening in the stomach was closed. As the stomach contents were widely distributed throughout the abdominal cavity and pelvis, it became necessary to extend the incision far below the umbilicus. The abdominal cavity was cleansed with large quantities of saline solution and then mopped dry, and the operation completed in the usual way. The patient made a good recovery.

In perforated gastric ulcer, when the opening in the stomach is large, there may be no external vomiting, the whole gastric contents being, as it were, vomited into the peritoneal cavity. In this case all the small intestine was red and inflamed. It is of supreme importance in all cases of perforation to operate before the onset of peritonitis; as in injury so here, the signs which should lead us to operate are not, and never ought to be, the signs of peritonitis. This patient has been well since his convalescence from operation. It is to be noted, then, that a gastro-enterostomy is not always necessary in the treatment of perforated gastric ulcer.

CASE 6.—Many years ago a barmaid was admitted to St. Thomas's Hospital with a perforated gastric ulcer of four days' duration. The perforation had occurred in the early morning when the stomach was empty; from that time until admission she had swallowed only neat gin. At the operation the small intestine was floating in gin; no peritonitis was found. She made an easy and rapid recovery. If you want to give your perforated gastric ulcer cases anything by the mouth, I therefore recommend to you the virtues of neat gin.

ACUTE APPENDICITIS.

The commonest illustration of an acute abdominal inflammation is acute appendicitis. On this subject Legueu well said:—

> Ask any surgeon, turn over the pages of any medical journal, and you will come across instances of those distressing cases where operation done too late has proved powerless to arrest the progress of lesions which have become too extensive. The prospect of spontaneous recovery and of medical treatment is a *decoy* to rely upon which is to be led into a snare; when once an appendicitis has commenced, whatever may be its aspect, we never know what it will become; and since the patient is now in any case condemned to operation at some time or other he may as well be assured of its benefits at once.
>
> To be quite just, opportunists—I mean opportunist surgeons—do not restrict themselves to systematic inaction. They have a lively dread of aggravation and do not abandon the patient to himself or even to medical treatment. On the contrary, they exercise a constant and minute supervision, they themselves see the case twice a day, and twice a day they examine the iliac fossa and pay attention to the pulse, the temperature, and the aspect of the patient. They are quite ready to intervene the moment that any indication of aggravation arises. They maintain that in this way they can forestall peritonitis or septicæmia.
>
> This line of conduct at first sight seems altogether rational. But in appendicitis all is deceptive and the most rigorous supervision may be found at fault for three reasons—(*a*) Because in the course of appendicitis there are often treacherous periods of calm; (*b*) because aggravation is sometimes so rapid as to derange all measures of precaution; (*c*) lastly, because the symptoms which reveal this aggravation are neither constant nor reliable. Even with the most rigorous supervision temporising exposes the patient to risk of irreparable damage. For some patients who have got well with medical treatment there are others who have died victims of this same medical treatment and of temporising.
>
> I hold, then, as injurious this practice of applying medical treatment in order to wait, watch, and operate should occasion arise. I have often regretted operating too late, but I have never had any occasion to repent of having operated too soon; early operation does away with all the dangers of temporising.

CASE 7.—The case of a girl aged 15 years, a near relative of mine, is an apt illustration. I saw her at 2 P.M. on a certain day last February. She had remained in bed during the morning, as she had been unable to sleep in the night and was not feeling well. When I saw her she had been sleeping and was drowsy, the face was flushed, there were uneasy sensations in the abdomen, the temperature was 100° F., and the pulse 90. I did not visit her again until 7 P.M., when I found the right side of the abdomen tender and moving irregularly with respiration. The drowsiness had persisted, the pulse was 110, and the temperature 101°. At 9 P.M. the intensely inflamed appendix was removed by Mr. G. H. Makins; there was already free fluid in the abdomen.

Would this case have been well treated by an opportunist surgeon? Would she have survived had the operation been deferred until the next day? The toxic infection in this case was the symptom which appeared to me the most grave.

This grave symptom, toxæmia, is also illustrated by the following case.

CASE 8.—Four weeks ago, about 6 P.M., a girl, aged 14 years, was brought to my house on her way home from a school on the south coast. Six weeks previously at the school she had had an attack of appendicitis with fever, vomiting, and abdominal pain, from which it was thought she had completely recovered. The last night at school she had not slept, and had again felt some pain in the abdomen. She had said nothing of this lest she should be kept at school. During the railway journey to London she had suffered from abdominal pain and nausea, and her mother said that she had not spoken a word. When I saw her she was drowsy, the face was flushed, and the tongue thickly furred; temperature 100° F., pulse 106. Decided tenderness over the right iliac fossa, and the muscles of this region remained immobile during respiration. Operation same night; appendix nearly gangrenous, free fluid in the abdominal cavity. For ten days after the operation the toxæmia continued, the symptoms being drowsiness without sleep, temperature 100°, pulse 100, very furred tongue, septic roseola of face and trunk, constipation, thirst, nausea, and vomiting. The vomit was small in quantity, and its odour was very foul. During this time she took only soda-water and repeated small doses of calomel.

Was I right in operating at once? Or would it have been better had the patient fallen into the hands of an opportunist surgeon? Other acute abdominal conditions which must be treated on similar principles are perforation of typhoid ulcer, duodenal ulcer, acute cholecystitis, and some forms of pancreatic disease.

Those who have visited Freiburg cannot fail to be struck with the great addition to our resources for dealing with the emergency of foreign bodies in the œsophagus and air passages that is afforded by the methods of direct bronchoscopy and œsophagoscopy.

ABSCESS OF BRAIN.

As an example of infective disease within the skull abscess of brain may be given. Operation should never be deferred when once the diagnosis is made, or is probable. I have known instances in which operation has been arranged for the next day, but the patient has died in the night.

CASE 9.—A man, aged 48 years, was admitted to hospital with chronic otorrhœa on the right side. He had lost a son a year previously from cerebellar abscess. The patient was a gardener, and said that for three weeks he had had slight headache and had once vomited. His main complaint, however, was that he had lost the sense of smell, being unable to distinguish in this way between roses and violets. On examination the right pupil was found to be stabile, and the right optic disc blurred. Operation forthwith. A large abscess in the right temporo-sphenoidal lobe was drained through its stalk, which was adherent to the diseased tegmen tympani. Rapid convalescence; no hernia cerebri; recovery of the sense of smell.

MOIST GANGRENE OF FOOT.—COMA.

Moist gangrene of the foot associated with glycosuria, and sometimes also with albuminuria, is a very dangerous disease, but is not always fatal. I have had more than one patient under my care with gangrene of the foot with these complications in whom amputation through the thigh was followed by recovery and the disappearance of both sugar and albumin from the urine. In such cases the urinary condition must be looked upon as secondary to the gangrene.

Coma, as we all know, occurs in patients with sugar in their urine, and it may follow some slight operation, such as an incision, and it always seems a hopeless and inaidable state, but on one occasion, many years ago, I succeeded in bringing such a patient back to consciousness before death ensued. The patient was bled from one arm to about a pint and at the same time saline infusion was commenced in the other arm. This was continued for several hours until nearly 20 pints of saline solution had been infused. The patient

regained normal consciousness for about 18 hours and during that time was quite competent to sign a will. Before the infusion commenced a soft catheter was passed into the bladder. It is very remarkable that at the conclusion of the infusion there was no urine in the bladder and none had escaped during the infusion. When the coma returned a second infusion had no effect. Similar treatment was recommended for the uræmia of Bright's disease by my late teacher, Dr. Charles Murchison.

CALCULOUS ANURIA.

Another emergency, of which not all surgeons have had experience, is calculous anuria. The suppression of urine comes on suddenly. It may remain absolute. I have had one case of this sort under my care.[3]

It is very remarkable that in most such cases, no matter how complete the suppression may be, the patient scarcely seems to suffer during the first seven or eight days, except perhaps from insomnia, slight nausea, and some failure of muscular strength. At the end of that time manifest symptoms of the effect of retained poisonous matters on the system arise and death occurs two or three days later. This is the usual history of calculous anuria which the surgeon must interrupt by operation at as early a stage as is possible. The modern methods of investigation will probably enable him to operate with much more confidence than was possible 20 years ago.

In calculous anuria the condition usually present is obstruction of one ureter and reflex inhibition of secretion in the other kidney; in some cases the other kidney is disorganised from old-standing disease. In either case operation should be performed upon the kidney last obstructed, to which the site of pain or of renal tenderness may be a guide.

Some remarkable recoveries from this condition have been recorded.

CASE 10.—Duret was called to a medical practitioner who had a second attack of calculous anuria a few days after he had spontaneously recovered from a first. The patient was much prostrated, and while Duret was present he had violent convulsions, the face became cyanosed, and the pulse small and irregular. Nephrotomy was done at once; no anæsthetic was required. Two large drainage-tubes were placed in the renal pelvis. During the night urine soaked through the dressing, and normal micturition commenced the next day. The patient recovered and resumed practice.

Chevalier performed nephrotomy on a woman, aged 63 years, on the fourteenth day of anuria; the patient was semi-comatose and her temperature two degress below normal. She recovered.

RENAL HÆMORRHAGE.

CASE 11.—Many years ago a costermonger, aged 45 years, tall, thin, and weatherbeaten, was admitted to St. Thomas's Hospital bleeding freely from the urethra. He had never before had any illness. The bleeding continued in spite of all measures taken to arrest it. It was obviously coming from the kidney, for numerous long clots, casts of the ureter, were passed. The right kidney, though not enlarged, was tender. By the fifth day he had become very anæmic and weak. An incision was made in the right loin; on drawing the kidney out through the wound it appeared healthy. On incising the pelvis it was found full of clot; this was removed. No angeioma or calculus was found. No further bleeding recurred and the man rapidly convalesced. In a week he left the hospital because I would not allow him to have a pint of brandy a day. It turned out that this man was a prince of costermongers; he owned 40 barrows, and he told me that as he was out in all weathers, by night and by day, he allowed himself a pint of brandy daily. I have never seen him since.

INTERNAL HÆMORRHAGE.

Surgical emergencies now cover a very wide field and a treatise, not a lecture, is required for their discussion. I have time to relate only a few more examples of emergency surgery.

As the study of inflammation is the foundation of pathology, so the surgery of the blood-vessels is the foundation of surgery. The principle of the treatment of hæmorrhage is that the bleeding vessel must be found at the site of injury and there tied or otherwise effectually secured. This was long practised in external hæmorrhage before any attempt was made to deal with internal hæmorrhage in the same way. Ligation of an artery in its continuity at some distance from the injured spot is only on rare occasions justifiable. Since the discovery that the great arteries may be successfully sutured it is no longer always necessary to destroy their continuity when wounded.

External hæmorrhage I must pass by, but I will cite one or two examples of internal hæmorrhage. The arrest of internal or concealed hæmorrhage is one of the great triumphs of modern surgery. Let us take a few examples from among many available.

Hæmorrhage into the abdominal cavity in large quantity occurs commonly from one of four conditions—ruptured tubal gestation, and rupture of the liver, spleen, or mesentery. The bleeding is rapid and profuse, sometimes so much so that death occurs before anything can be done, but in some cases a few hours are allowed during which life can be saved.

RUPTURED TUBAL GESTATION.

Ruptured tubal gestation is one of the commonplaces of ordinary practice. These cases sometimes come into the general surgical wards as cases of peritonitis. There is generalised tenderness over the abdomen which has come on so rapidly since the commencement of the illness that, as Cullingworth pointed out, it cannot be due to inflammation. There are the usual signs of hæmorrhage, but this superficial tenderness is the one sign I wish to emphasise.

How simple is the treatment! An abdominal incision is made, blood and clots gush out, the hand is introduced through a mass of clot, the fingers seize the ruptured bleeding tube, and so arrest the hæmorrhage. At the same moment saline infusion is begun in the vein of the arm, for it is futile to practise infusion while the injured vessel is still unclosed.

RUPTURED SPLEEN.

Take again a case of ruptured spleen such as the following:—

CASE 12.—A boy, aged 10 years, fell through a height of about 10 feet on to some large stones against which he struck his left side. When seen he was pale, pulse 130, and temperature 100·8° F. He was very restless, respiration thoracic, shallow and quick, alæ nasi moving. Abdomen distended and immobile; no clear resonance anywhere, so that it could not be ascertained whether or not the dulness in the loin disappeared on turning the patient over on to the other side. Immediate operation found the belly full of blood and the spleen completely torn across. The pedicle was seized and the ruptured spleen removed; the clots were cleared away and the wound closed. The patient made a good recovery.

HÆMORRHAGE FROM THE HEART.

No more formidable example of thoracic hæmorrhage can be chosen than that of hæmorrhage from the heart. Ovid[4] said: "By no resource can wounds of the heart be healed"; and Billroth, only a quarter of a century ago, wrote: "Let no man who hopes to retain the respect of his medical brethren dare to operate upon the human heart." Yet since Billroth's time more than 150 cases of attempted suture of wounds of the heart have been recorded with 30 to 40 per cent. of recoveries. Schnitzler's case is a good example:—

CASE 13.—A male, aged 16 years, attempted suicide by stabbing himself with a large pocket-knife over the heart. When seen there was a wound about 1½ cm. long near the left nipple; there had not been much external escape of blood, but the patient was blanched and had a feeble and quick pulse. About three-quarters of an hour after the injury morphia was given hypodermically and the patient placed under chloroform. The chest was opened by enlarging the wound and removing the fifth costal cartilage up to the sternum. The left pleura had been wounded by the stab, and air and blood escaped from it. About 3 cm. of the fourth costal cartilage was then removed, and a second incision made at right angles to the first. A transverse wound was found in the pericardium. This was enlarged and held open; a wound of the right ventricle

[3] This condition was first treated by operation by Mr. Lucas at Guy's, October, 1885.

[4] "Sanäbit nulla vulnera cordis ope." Ovid was a sentimental fellow, not a surgeon, and he may have been referring to those wounds of the heart which were no doubt as frequent in his day as in ours, but which no surgeon inflicts and which the art of surgery is powerless to cure.

near the septum was disclosed. It was plugged with a finger of the left hand and closed by silk sutures. The pericardium was cleared of clots and then sutured; the pleura was drained. The patient afterwards had pneumonia on the right side and empyema on the left, for which latter the usual operation was performed and he made a good recovery.

In 1882 Bloch, of Berlin, studied in animals the healing of wounds of the heart and so laid the foundation of cardiac surgery. The first successful suture of a wound of the heart was done by Rehn in 1897. Not only stab wounds but gunshot wounds of the heart have been successfully operated on. Dupont collected 31 cases: in 11 death was immediate, so that nothing could be attempted; in 20 operation was done, and 8 survived the immediate effects of the operation.

WOUND OF PULMONARY ARTERY.

In the following case, reported by Mauclaire, a wound of the pulmonary artery was found.

CASE 14.—A male, aged 17 years, had been stabbed with a triangular file. There was a wound in the third left intercostal space, not bleeding externally. The cardiac dulness was much enlarged, and there was pneumothorax on the left side. On operating, air and blood were found in the left pleura. There was a wound in the upper part of the anterior surface of the pericardium corresponding to that in the skin. On enlarging the pericardial wound, a wound in the pulmonary artery was found. The edges were seized with Kocher's forceps and the wound was closed with three perforating sutures. The patient bore the operation well, but hæmorrhage into the thorax recurred next day, and the patient died. The condition of the wound in the artery was not ascertained.

REMOVAL OF CLOT FROM PULMONARY ARTERY.

Perhaps the most astounding instance of vascular surgery is the removal of clot from the pulmonary artery. This was done by Trendelenburg.

CASE 15.—Trendelenburg's patient was a man, aged 45 years, in the early stage of tabes, who slipped and fractured his left femur. One day about a month after the accident he had a slight rigor, and a quarter of an hour later he had sudden dyspnœa and cyanosis. For 10 or 15 minutes he seemed to improve, and then suddenly got so much worse that death was evidently imminent. In this emergency an attempt at surgical relief was made.

The pleura was opened at the level of the second rib, and through the pleura the pericardium was opened at the level of the third rib; the aorta and pulmonary artery were held up with a curved sound. These vessels no longer pulsated, and only slight and irregular contractions of the heart were to be seen, and the breathing ceased almost directly. The pulmonary artery was compressed by traction on the sound, an incision was rapidly made in the vessel, and the wound dilated. With a polypus forceps a thrombus 34 cm. long was extracted. The forceps was again introduced three times in rapid succession, and three other smaller thrombi brought away; after this came fluid blood.

Tetanic twitchings of the body muscles showed the urgent need of oxygen for the brain. The lips of the wound in the pulmonary artery were held together with forceps, the constriction of the aorta and pulmonary artery was removed, and artificial respiration was commenced. Natural breathing soon was resumed, and the pulsation of the aorta and pulmonary artery at once recommenced. The wound in the pulmonary artery was sutured. Troublesome bleeding occurred from the internal mammary artery. Before closing the external wound the Roth-Dräger apparatus was applied to get rid of the pneumothorax.

On recovery from the anæsthetic the patient was breathing fairly quietly, but the pulse, though fairly strong, was 120–140. Until the next morning the patient seemed to be doing well. From that time the condition became gradually worse, and death occurred 37 hours after the operation.

At the necropsy a thrombus about 5 cm. long was found in the left branch of the pulmonary artery, and in a small branch of the right pulmonary artery was another small clot. The wound in the pulmonary artery was securely closed. There was no blood in the pericardium. In the left pleura was a considerable quantity of fluid blood, the greater part of which had apparently come from a secondary hæmorrhage from the internal mammary artery, which had not been perfectly secured.

Trendelenburg says:

> The necropsy left no doubt that the emboli came from the right femoral vein. Probably they entered the pulmonary artery in three divisions. The slight rigor with which the attack began was caused by a small embolus like that found at the necropsy in one of the minor divisions of the right pulmonary artery; then came larger clots which possibly came from the iliac vessels. These cut off a considerable area of the lung from the pulmonary circulation, and led to the first severe attack of dyspnœa, heart weakness, and anxiety. Some improvement took place in these symptoms, perhaps because a particular disposition of the emboli allowed the increased heart's action to send blood to more of the pulmonary capillaries. Lastly, came the long thrombus which almost completely blocked the main trunk. The closure was not absolute when the operation was commenced, for had it been so pulse and respiration would have ceased earlier. From the time when the respiration suddenly became worse to the moment of incision of the pulmonary artery ten minutes only elapsed.

When I was in Leipzig Professor Trendelenburg kindly demonstrated at my request on the dead body the method of operation. I have practised this operation on the cadaver but have not done it on the living. I show you Trendelenburg's instruments. It has been found experimentally that the aorta and pulmonary artery must not be obstructed for more than a minute and a half, but I found that in the post-mortem room 40 to 45 seconds is ample time in which to complete the manipulation. The pleura can be pushed aside and need not be opened.

The progress of thoracic surgery is wonderfully illustrated by Trendelenburg's operation. The formidable complications barring advance in this region of the body have been the occurrence of pneumothorax and collapse of the lung. In the future thoracic surgery will be set free from these dangers. Willy Meyer, for example, has successfully resected experimentally the intrathoracic portion of the œsophagus in a chamber in which it was possible to operate either under positive or under negative differential pressure or under a combination of the two; and ere long we may hope that surgery will be as useful in disease or injury of the lung and heart as it is in like conditions of the abdominal organs.

INTRACRANIAL HÆMORRHAGE.

In the head the question of the treatment of hæmorrhage is not so much one of securing a bleeding vessel as one of relieving pressure on the brain and allowing the extruded blood to escape. The amount of an intracranial hæmorrhage, viewed as mere loss of blood, is but seldom formidable.

The treatment of the intradural hæmorrhages of the newly born is one which has not, as yet, very freely permeated the profession, but it is of great importance, for if these infants survive they must be the victims of palsy, epilepsy, or mental defects. The treatment by craniectomy has been shown by Harvey Cushing to be very satisfactory. The diagnosis in characteristic cases is not difficult. Inability to suck, post-natal asphyxiation, a bulging fontanelle without pulsation, convulsions, unilateral palsy, subconjunctival hæmorrhage, and proptosis oculi were the most prominent symptoms in Cushing's cases.

In some cases of ordinary cerebral apoplexy I think the immediate danger to life might be averted by lumbar puncture or repeated lumbar puncture. The cerebral hæmorrhage is associated with an increase of cerebro-spinal fluid. In a recent experience I withdrew on two occasions 1½ oz. of blood-stained fluid, on the first occasion with marked relief of symptoms; headache and restlessness disappeared and five hours' sleep was obtained.

In heat apoplexy, which may be described as a hæmorrhagic meningitis serosa, lumbar puncture may be curative, as the following case shows.

CASE 16.—A man, aged 53, in one of the hottest days of July, when exposed to the sun, became unconscious suddenly. With care and ice to the head he had recovered three days later, but complained a good deal of headache as he lay in bed. The next day a relapse took place, and on the fifth day he was again completely unconscious. On the sixth day I saw the patient with Mr. A. S. St. John, of Eltham. He was completely comatose, Cheyne-Stokes breathing, temperature 104° F., pulse 60, urine and fæces passed in bed. Lumbar puncture was done and 1½ oz. of pink fluid were withdrawn. In 12 hours consciousness had completely returned. Four days later a relapse took place and complete coma again supervened. Lumbar puncture was successful a second time. Consciousness returned in a few hours and the patient from this time made an uninterrupted recovery.

In apoplexy with resultant paralysis and other symptoms it has been shown that the capsular clot can be removed, or

rather removes itself by extrusion, when an incision is made in the brain. Such symptoms as hemianæsthesia, aphasia, word-blindness, &c., have cleared up after removal of the clot.

ARTERIO-VENOUS ANASTOMOSIS.—SUBCLAVIAN ANEURYSM.

The wonderful work of Carrel and Guthrie has made it possible to anastomose an artery with a vein. Gluck was the first successfully to perform arterio-venous anastomosis in man. Until this advance was made the emergency of senile gangrene usually necessitated amputation through the thigh. Now the femoral artery may be anastomosed with the femoral vein, and the venous system thus made to carry arterial blood to the foot. In this way the gangrene may be arrested and the limb saved.

In conclusion, let me show you a picture of a patient whose innominate artery I successfully tied two months ago for the relief of subclavian aneurysm. What would John Hunter have given to be present at this operation?

THE FUTURE OF SURGERY.

The science and art of surgery in my lifetime have achieved what in my student days would have been looked upon as but the most magnificent promises of impossibilities. Kindled by the past, we can look forward with confidence. In groping our onward way "upon the bank and shoal of time" to clearer knowledge in the mysterious world of disease, let us listen a moment to, and derive inspiration from, the words of Paracelsus:—

> I go to prove my soul!
> I see my way as birds their trackless way.
> I shall arrive! what time, what circuit first,
> I ask not: but unless God send his hail
> Or blinding fireballs, sleet, or stifling snow,
> In some time, His good time, I shall arrive:
> He guides me and the bird. In His good time!

Can we venture to forecast the future of surgery? Can we

> Look unto the seeds of time
> And say which grain will grow and which will not?

Surely the ancient prophecy that "many shall run to and fro, and knowledge shall be increased" is being fulfilled in our own time and will continue to be fulfilled in the time to come. "There are many events in the womb of time which have yet to be delivered."

> For these things tend still upward, progress is
> The law of life, man is not Man as yet.

Researches
INTO
SENSORY DISTURBANCES FROM CEREBRAL LESIONS.*

BY HENRY HEAD, M.D. CANTAB., F.R.S.,
PHYSICIAN TO THE LONDON HOSPITAL;
AND
GORDON HOLMES, M.D. DUB.,
ASSISTANT PHYSICIAN TO THE NATIONAL HOSPITAL, QUEEN-SQUARE, AND TO THE SEAMEN'S HOSPITAL, GREENWICH.

(Concluded from p. 83.)

III.—SENSORY DISTURBANCES PRODUCED BY LESIONS OF THE CEREBRAL CORTEX.

In describing the effect of a cortical lesion upon sensibility we shall proceed exactly as with lesions of other parts of the nervous system. All such expressions as "cutaneous sensation" and "light touch" will be strictly avoided, and we shall deal as far as possible with measured stimuli only. Thus, for instance, we shall not speak of "deep sensibility" as preserved or lost, but shall give the exact stimuli used and the form of response they evoked.

1.—GRADUATED TACTILE STIMULI.
(Von Frey's Hairs and Pressure Æsthesiometer.)

Lesions at lower levels of the nervous system produce, on the whole, forms of altered sensibility which react with remarkable constancy to graduated stimuli. A touch of definite intensity, if sufficiently strong to evoke a sensation, will do so in a large proportion of instances, while some less intense stimulus will cause no sensation of any kind. Somewhere between these two we are justified in placing the threshold for tactile sensibility.

But the characteristic change produced by a cortical lesion consists essentially in a want of constancy and uniformity of response to the same tactile stimulus. Increasing the stimulus does not necessarily improve the patient's answers, and in many cases a threshold cannot be obtained. On attempting to obtain a maximum threshold on the affected hand we meet with the same curious irregularity of response that has hampered all who have attempted to use graduated stimuli in such cases; the patient seems to be untrustworthy. At one time he responds to a hair of 21 grm./mm.^{2}; at another even 100 grm./mm.^{2} produces no effect. Not only are his answers apparently incalculable, but not infrequently he responds when he has not been touched.

This irregularity has led most observers to reject all graduated stimuli and to adopt some other form of tactile stimulation, such as rubbing with the finger or with cotton-wool, to which the answers are more uniform. But in this irregular response to graduated tactile stimuli lies the key to the sensory disturbance produced by lesions of the cerebral cortex.

We have modified the method of examination in the following manner so as to bring out the true nature of this phenomenon. A hair is selected producing a stimulus just above the maximum threshold, to which the normal hand reacts with constancy when it is applied 16 times in the minute. If the same hair is applied in the same manner to a corresponding part of the affected hand the responses are irregular and wanting in uniformity. Then more powerful hairs are used up to those exerting many times the pressure. Still the response remains irregular; in fact, the answers may be less accurate with the more powerful stimulus than to the finer hairs. But further stimulation with the hairs of lower grade does not of necessity materially reduce the proportion of correct answers. The irregular response to the more powerful hairs cannot, therefore, have been due to fatigue alone.

We are, therefore, compelled to use some other form of measurable stimulus, and choose the pressure æsthesiometer, in which measured weights may be brought to bear on a surface of 3 mm. in diameter. In one of our cases the normal hand responded constantly to a pressure of 2 grm., the minimum weight we could apply with this apparatus. But on the abnormal hand the answers showed the same remarkable tendency to irregularity that was present when it was stimulated with graduated hairs. Here it is impossible to say that any tactile threshold can be obtained in the sense usually given to the term. A part that was sensitive to a hair exerting a pressure of 0·36 grm. was not constantly sensitive to a pressure of 30 grm.

This uncertainty of response is not the only peculiarity met with in examining the affected part with measured tactile stimuli. Fatigue is induced with unusual facility, and a part that has responded in the characteristic manner to one of the less powerful hairs may fail altogether to respond to 100 grm./mm.^{2} This is, however, an extreme reaction seldom, if ever, seen in uncomplicated cortical cases.

Another disturbing factor in the response to graduated tactile stimuli is the occurrence of hallucinations, or replies that are not the direct sequel to a stimulus. We believe that this tendency to hallucinate is not due to any general untrustworthiness on the part of the patient, but is another aspect of the irregular response characteristic of cortical loss. On one occasion a patient gave so many hallucinatory answers to graduated hair-stimulation of the affected hand that all testing became impossible. But in spite of this "untrustworthiness" the answers obtained from the normal hand and from the soles of both feet were excellent, and in each of these parts a perfect threshold could be worked out.

Many of our patients are highly intelligent; if they are asked to describe their sensations at the time they are hallucinating, introspection leads them to remarkably similar conclusions. They start by saying that a sensation from the affected part differs from that evoked by the same stimulus on the normal hand or foot. The hair seems to remain in contact with the skin, and after a series of touches a continuous sensation is produced. Upon this continuous sensation each consecutive touch may or may not produce

* These Researches appear in complete form in Brain, vol. xxxiv., 1911.

that additional change recognised as a fresh contact. But at times the sensation interpreted as another contact may arise without actual stimulation, and sometimes it may even recur several times. These hallucinations are, in fact, the direct consequence of that persistence of sensation so frequently a feature of the changes produced by a cortical lesion.

Frequently tactile sensibility is less grossly affected by a cortical lesion. The response may still be irregular and the sensation of contact may persist, but with stronger stimuli the proportion of replies increases until, perhaps, every contact may evoke an answer. Under such circumstances the affected part may exhibit unusual signs of fatigue, although general attention, shown by the response on the normal side, has undergone no diminution. Moreover, the sensations of contact tend to persist, and hallucinations may break an otherwise perfect series of replies.

Whenever a tactile threshold can be obtained, sensibility as a whole is comparatively slightly affected. No form of sensory appreciation is completely lost, and some approximation to a threshold can be discovered with other graduated tests, such as the compasses.

We can sum up the conclusions to which we have arrived as follows:—

1. A cortical lesion may reduce the accuracy of response, from the affected part, to graduated tactile stimuli. The form assumed by this defective sensibility differs from that produced by lesions at other levels of the nervous system. The affected part may respond to the same graduated hair as the normal hand; but this response is irregular and uncertain. Increasing the stimulus may lead to no corresponding improvement, and even the strongest tactile hair may occasionally evoke less certain answers than a hair of much smaller bending strain. Moreover, a touch with the unweighted æsthesiometer may be as effective at one moment as the same instrument weighted with 30 grm. at another. In such cases no tactile threshold can be any longer obtained.

2. This irregularity of response is associated with persistence of the tactile sensation and a tendency to hallucinations of touch. Where the sensory defect is not sufficiently gross to abolish the threshold, persistence, irregularity of response, and a tendency to hallucinate may still disturb the records.

3. In all cases where tactile sensibility is affected, whether a threshold can be obtained or not, fatigue is induced with unusual facility. Although the patient may cease to respond to tactile stimuli over the affected part in consequence of fatigue, his answers will remain as good as before from the normal parts. The fatigue is local and not general.

4. With stationary cortical lesions, uncomplicated by states of shock or by diaschisis, sensibility to touches with cotton-wool is never lost over hair-clad parts. Over hairless parts stimulation with cotton-wool may produce a sensation which seems "less plain" to the patient, and his answers may show the same inconstancy so evident when he is tested with graduated tactile stimuli.

2.—MEASURED PAINFUL STIMULI.

In all lesions of the sensory path below the optic thalamus some loss of sensation to painful stimuli is of common occurrence. But we have never discovered any disturbance of this form of sensibility as the consequence of a stationary cortical lesion, except when the lesion was recent or unless the patient had suffered recently from convulsions, or had been subjected to other causes of shock.

A prick is the only effective means of applying a measurable painful stimulus to the skin. But all mechanical means for measuring the force needed to evoke a sensation of pain when a sharp point is thrust into the skin labour under the same disadvantage. Any sharp object, such as a needle, produces first of all the recognition that the stimulus is pointed: further pressure adds to this a sensation of pain. Now it is almost impossible to prevent the ordinary patient from saying that he is pricked whenever he appreciates that the stimulus is a sharp point, and if he is told to wait until he obtains a sensation of pain we run the risk of placing the threshold too high.

Usually the patient can discover no difference between two pricks of the same force applied to similar portions on the two sides of the body, but occasionally he states that the stimulus is "plainer" or "sharper" on the normal than on the abnormal part. This difference in sensation is accompanied by no raising of the threshold either to prick or to painful pressure. The readings obtained with the prick-algesimeter, or with the pressure-algometer, are the same on the two sides. Moreover, the patient shows no more signs of discomfort from the one side than from the other, with the same stimulus. We therefore believe that this want of "plainness" or "sharpness" of which the patient may complain is due to a want of distinct appreciation of the pointed nature of the stimulus; that is to say, the want of "plainness" or "sharpness" is not due to a diminished sensibility to the painful aspect of the prick.

The pressure-algometer gives a measure of discomfort rather than pain. To this coarse stimulus the affected part responds as readily as the normal, and we have found none of that over-reaction so prominent a feature with lesions of the optic thalamus.

Thus pure cortical lesions cause no increase or decrease of sensibility to measured painful stimuli. But if the cortical destruction is recent or progressive, or if it produces convulsions, however slight, remarkable defects may appear in painful sensibility. The threshold, not only to prick but to painful pressure, may be considerably raised, and sometimes even coarse pricking may fail to evoke a sensation with any certainty. In fact, we may be face to face with a truly diminished sensibility to painful stimuli closely resembling the loss produced by interference with sensory impulses at a lower level. These changes are due to shock, exhaustion, and to the state called by Monakow "diaschisis." They are due to a profound disturbance of function extending back beyond the level of the sensory cortex and affecting even the receptive mechanism in the optic thalamus.

In conclusion, a pure cortical lesion leads to no change in the threshold to measurable painful or uncomfortable stimuli. Nor does the patient express greater dislike to these stimuli on one side than on the other. A prick may be said to be "plainer" or "sharper" on the normal than on the affected side, but this is due to a defective appreciation of the pointed nature of the stimulus and bears no direct relation to the painfulness of the sensation evoked.

3.—TEMPERATURE.

Many cortical lesions produce no change in the response to thermal stimuli, provided those periods of shock which follow an operation or an epileptiform seizure are strictly avoided. In other cases, however, we found definite changes in the sensibility of the affected parts to heat and cold, although the lesion had remained quiescent for many years. In every case the nature of the disturbance in sensation was similar, and consisted essentially in an increase of the range within which a thermal stimulus was thought to be neither hot nor cold. Normally this neutral zone varies greatly under different conditions and in different persons. It usually occupies from 2° to 5° C., but its position on the scale shifts with the external temperature. At any moment it can be raised or lowered by warming or cooling the hand; but although the position on the scale may be shifted by adaptation the interval in which a thermal stimulus is thought to be neither hot nor cold is materially altered.

Fortunately, in all our cases we were able to compare the behaviour of the normal and the affected sides of the body under the same conditions and with equal care. Now, whenever the appreciation of thermal stimuli was affected by a cortical lesion, this neutral zone extended over a greater number of degrees than on the normal hand. Not only is the range of the neutral zone increased, but the responses from the affected hand are slow and irregular compared with those obtained from normal parts under similar conditions. Moreover, the power of comparing two thermal stimuli, applied either together or in sequence, may be diminished. Here, as with the defects of tactile sensibility, it is the power of discrimination, the faculty of comparing two stimuli with one another, which is disturbed by cortical lesion. The only actual loss of sensation, therefore, falls upon that part of scale where thermal recognition habitually depends on some previously existing standard. In conclusion, we find that the appreciation of heat and cold was not affected in a considerable number of cortical lesions. But whenever thermal sensibility was disturbed the following changes were found:—

1. The neutral zone, within which the stimulus was said to be neither hot nor cold, was considerably enlarged in comparison with that observed on similar normal parts of the same patient.

2. The patient complained that, although he recognised correctly the nature of the stimulus, it seemed "less plain" than over normal parts. His answers were less constant and less certain; a temperature recognised without difficulty at one time seemed doubtful at another.

3. The power of discriminating the relative coolness of two cold stimuli or the relative warmth of two hot tubes may be diminished. Thus 20° C. may be said to be the same as ice, although both are uniformly called cold, and 40° C. may seem as warm as, or even warmer than, 48° C. The faculty of appreciating the relation to one another of two temperatures on the same side of the scale is disturbed.

4.—THE APPRECIATION OF POSTURE AND OF PASSIVE MOVEMENT.

Inability to recognise the position of the affected part in space is the most frequent sensory defect produced by lesions of the cerebral cortex. In some cases this and the allied faculty of recognising passive movement may be the only discoverable abnormalities. Whenever sensation is disturbed at all these two forms of spacial recognition will be certainly affected. Since some disturbance of the power of recognising passive movement always accompanies defective postural recognition, these two kindred faculties will be dealt with together in this section.

(*a*) *Recognition of Posture.*

In most cases of cortical disease, the usual rough method of testing is amply sufficient to demonstrate defective appreciation of posture. The patient's eyes are closed, and the affected limb is placed in some position different from that in which it lay at first. He is then told to touch some part of it, such as the index finger, with his normal hand. At first he usually fails to find the limb; when at last he strikes some part of it he moves his indicating hand down to find the finger he was asked to touch. Should the power of localisation remain intact he can ultimately grope his way to the exact spot; but if localisation is also affected, although he may reach the hand, he will probably be unable to find the finger.

So gross is the defective recognition of posture in most cases that this method amply suffices to demonstrate it in an unequivocal manner. Horsley [10†] has, however, introduced a useful means of measuring this deviation from the normal. The finger to be tested is applied to the one surface of a glass plate divided by lines into measured squares, and with the free hand the patient seeks to indicate on the other surface of the plate the position of the finger he is seeking. Ths results of his attempts can be read off on the measured plate. Instead of this glass plate we have used a piece of stiff cardboard. In the centre of the one surface of this cardboard is a slight depression to receive the tip of the index fever, and on the other a sheet of white paper can be fixed. With the normal hand the patient seeks to indicate the position of the affected finger, which remains at rest in the depression. The point upon which he ultimately settles is marked on the paper. His indicating hand is then withdrawn, and he is asked to make another attempt. Each record of a series of observations made in this way can be measured and collated at leisure.

In every case where sensation was disturbed in any way, however slightly, as the result of a cortical lesion the records with Horsley's plate showed some loss of postural appreciation in the affected hand. This method, therefore, forms a delicate means of detecting sensory changes of cortical origin.

The deviations discovered by Horsley's method, even in normal individuals, are so considerable that it is necessary to have some standard in each patient with which to compare the records obtained from the affected parts. It might be objected that most cortical lesions produce so much paralysis that the affected hand cannot be used to point out the position of the normal forefinger. But in spite of its paresis and defective sense of posture, the records obtained when the affected hand sought the normal forefinger were uniformly better than when the patient attempted to point to the affected forefinger with his normal hand. That is to say, defective appreciation of the position of the hand to be sought for has a more disturbing effect upon the records than weakness and loss of postural sense in the indicating hand.

† These and other reference numbers relate to a bibliography at the end.

All these tests depend on knowledge of the position in space of the extremity as a whole. To what extent its separate segments are affected can only be discovered by asking the patient to imitate, as exactly as possible with his normal limb, the posture of the affected part. His eyes are closed and, whilst his attention is diverted by conversation, some part such as the index finger is moved into the desired position. After an interval he is asked to place his normal index in the same position as the index of the opposite hand. By this means we have been able to confirm the statements of most recent writers that the gravest loss produced by a cortical lesion is usually found in the extremity of the limb (Goldscheider [9], Petrén, Bergmark [1]).

(*b*) *Recognition of Passive Movement.*

The inability to recognise posture is always associated with diminished appreciation of passive movements, in some cases so great that even complete flexion and extension of a joint cannot be recognised. Here no measurement is required; the loss of appreciation is absolute. But whenever the loss is less gross we agree with Petrén and his fellow-workers that the smallest movement which can be appreciated by the patient must be measured; such measurement alone can demonstrate whether this faculty is or is not affected.

Measurements only can furnish us with the materials for determining the relative extent to which the appreciation of passive movement is disturbed at the various joints of the affected limb, and in cases where the condition of the patient is changing they may form a useful record of the progress of the disease. But when we attempt to measure the extent of the smallest appreciable movement, two different phases of recognition must be distinguished. The patient may say at once when he thinks a movement has occurred; this gives the measure of the least perceptible movement. Or he may wait until he is able to indicate its direction. As a rule, in the normal limb most patients wait until they can recognise the direction of the movement before they say that the joint has been moved; but the difference between the point at which the movement is appreciated and that at which its direction is recognised is normally small. In the abnormal limb, however, this distance is greatly exaggerated, and movements may be perceived long before their direction can be recognised. It is, therefore, important to record both the extent of the smallest movement perceived and the range necessary to evoke recognition of its direction.

All cortical lesions which produce any change in sensibility lessen the power of appreciating passive movements and the knowledge of their direction. In every case this loss was associated with a concomitant disturbance of the recognition of posture. In all our cases the loss was greatest towards the distal portions of the limb; in this it corresponds exactly with the disturbance of the sense of posture. Here we can only confirm the work of almost every previous observer.

In conclusion, we find, like most of our predecessors, that—

1. Cortical lesions most frequently disturb the recognition of posture and of passive movements. Whenever sensation is in any way affected in consequence of a cortical lesion these two functions suffer.

2. In all our cases the disturbance in the faculty of recognising posture and passive movements was greater towards the peripheral parts of the affected limb.

3. When a patient with unilateral disturbance of these faculties attempts to point to some part of his body, defective knowledge of its position causes greater error than want of recognition of posture and movement in the hand with which he points.

4. When testing the patient's power of appreciating passive movement the answers are frequently uncertain and hallucinations of movement may occur. And yet the patient may be remarkably consistent and accurate when normal parts are tested.

5.—LOCALISATION.

By localisation we understand the power of recognising correctly the spot that has been stimulated, and it would seem at first sight that little difficulty could arise in discovering whether this faculty was affected or not, but a good deal of confusion exists owing to technical difficulties inherent in the methods usually employed to investigate the power of localisation.

Of all the methods at present in use that of Henri is probably the most suitable. Excellent and simple as we

found this method it labours under one serious defect for clinical purposes, as ordinary patients were liable to become confused when asked to point out the spot stimulated on a diagram, picture, or even on a photograph of the hand. We therefore adopted the following modification, which we found to be a great improvement on the original Henri method. The hand to be tested, for example the left, is hidden from the patient's sight with a screen. One of us standing behind places his own left hand in a similar position in full view of the patient, who indicates on this living model the situation of the place where he believes he has been touched. A second observer marks on a life-sized diagram the position of the stimulated spot and the point indicated by the patient. This method we have employed throughout this work. It avoids both the technical difficulties of spot-naming and the fallacies of the groping method, and is peculiarly useful in clinical investigations.

The uncertainty and irregularity of response to tactile and pressure stimuli, so common a consequence of cortical lesions, are liable to lead to fallacious results when testing the power of localisation. We usually, therefore, touch the spot with some blunt instrument of neutral temperature, and continue the touches until the patient says he appreciates the contact. He then indicates on the hand of one of the observers the situation of the stimulated spot.

The power of recognising the position of a spot stimulated is comparatively seldom affected as a consequence of pure cortical lesions, provided all periods of shock are avoided. Most seizures, and all operations on the brain, are followed by temporary loss of this function grossly in excess of anything found with stationary lesions of the cortex. The methods we have employed enable us to discover whether the power of localisation is intact or not, although the patient is entirely ignorant of the position of the affected limb; even when this is so every part of the affected hand may be touched in succession without a single mistaken answer. But should localisation be affected scarcely a single stimulus is referred to its correct position, and the patient frequently complains that he has "no idea" where he has been touched.

We cannot insist too strongly that when localisation is defective from lesions of the cortex the stimulus is not localised in some false direction, but the patient has a vague and uncertain idea amounting in some cases to complete ignorance of its position. Erroneous localisation is not due to the uncertainty in tactile appreciation so commonly produced by a cortical lesion; for it is equally manifest when the stimulus that the patient is asked to localise is a prick about which he is never in doubt. Defective localisation is not a necessary concomitant of the defective recognition of posture so commonly produced by cortical lesions. In several cases where the appreciation of position and passive movement was gravely affected localisation was demonstrated to be perfect by every method except that of groping for the stimulated spot. The faculty of localising the stimulated spot as determined by all methods except groping is less often affected by a cortical lesion than the power of appreciating posture. In fact, we have not yet seen a case in which localisation was disturbed without a coincident loss in postural recognition.

The conclusions to which we have arrived in this section may be summed up as follows:—

1. The power of localising the stimulated spot is not commonly lost as a consequence of cortical lesions.
2. This faculty is independent of the power of recognising the position of the affected limb; appreciation of posture may be lost, although localisation is not in any way disturbed.
3. If the power of localisation is lost the patient will be unable to recognise not only the position of a spot touched, but also the position of a prick.
4. When localisation is defective the patient does not habitually localise in a particular direction, but ceases to be certain where he has been touched or pricked.

6.—THE COMPASS-TEST.

Loss of the power to distinguish two points applied to the skin simultaneously is one of the most striking changes produced by cortical lesions. It is not present in every case; the patient may have difficulty in recognising the posture of the affected limb, and the appreciation of passive movements may be diminished, yet the compass-test may yield equally good results on the two sides. But with the larger number of cortical lesions the discrimination of two points will be affected. It may be, in the milder cases,¶ that the threshold is raised; to these we shall return later. More commonly no threshold can be obtained even by separating the limbs of the compasses to the widest extent possible within the limits of the principal segments of the affected limb. If a bad record is obtained when the points are 5 cm. apart, widening the distance to 20 cm. may cause no material improvement. Decreasing the difficulty of the problem does not of necessity improve the accuracy of response; estimation of a threshold has become impossible.

Any defect in tactile sensibility is liable to disturb the compass-records. When, therefore, we consider the peculiar changes described in the section on graduated tactile stimuli, the loss in discrimination of two points might appear at first sight to be due to diminished tactile acuity. This cannot, however, be the cause of the defective compass-records; for the inability to distinguish two points applied simultaneously is equally definite if each limb of the compasses is armed with a needle and two pricks replace the two tactile stimuli. We have already seen that the recognition of a prick is never destroyed in consequence of a cortical lesion, and sensibility to pain undergoes no changes analogous to those of tactile sensibility. It is, therefore, obvious that the power of recognising "two-ness" is a separate function of sensation which may be destroyed by a cortical lesion. This loss is not dependent on the changes in tactile sensibility, though the two defects are strictly analogous phenomena.

Not every cortical lesion produces a severe loss of compass-discrimination. Although the recognition of posture is disturbed, the compass-records may remain equally good on the two sides; but as soon as tactile sensibility shows any of the changes produced by a lesion of the cortex the power of distinguishing two points will also suffer. Sometimes, in cases where sensation is little disturbed, it is possible by widening the distance between the compass-points to obtain a perfect record over the affected part; a true threshold can then be discovered. But the records tend to be confused by the same irregularity and uncertainty of response so characteristic of the disturbed tactile sensibility in these cases of cortical disease.

We may conclude from the observations described in this section that—

1. A cortical lesion may destroy the power of discriminating two compass-points, both when applied simultaneously and successively. If this is the case, no threshold can be obtained for either form of the test; increasing the distance between the points does not constantly improve the accuracy of the answers.
2. This disturbance is not dependent on changes in tactile appreciation, for it can be demonstrated equally well with two painful as with two tactile stimuli.
3. The condition of tactile sensibility and the accuracy of the simultaneous compass-test are closely associated; a raised tactile threshold is usually accompanied by a raised threshold for the appreciation of two points simultaneously applied.
4. Should the power be preserved of recognising two points when the compasses are applied consecutively, localisation will be found to be intact. The patient's appreciation of the two points when they are separated by an interval of time is due to the recognition of the separate locality of the two spots touched.

7.—THE APPRECIATION OF WEIGHT.

This test has been too frequently neglected in clinical work, probably because it demands considerable care on the part of the observer and goodwill in the patient. When carefully carried out no test is more satisfactory, for the results can be expressed in a numerical relationship, and when the faculty of recognising differences in weight is disturbed the errors, compared with those of the normal hand, are enormous.

There are several ways of conducting this test which have been fully described elsewhere. But at the highest sensory level the appreciation of difference in weight depends mainly upon two faculties. When a weight placed upon the fully supported hand is either increased or diminished, the recognition of the change is based on the power of appreciating differences in pressure. To estimate the relation between two weights placed upon the hand one after the other requires, however, not only an appreciation of pressure, but

also the power of relating some consequence of the first weight with the immediate effect of the second weight. Lastly, when a weight is placed at the same moment in each palm, and the patient is allowed to "weigh" the two objects against one another, he depends mainly upon his power of estimating movement and posture.

Cortical lesions usually diminish the accuracy of the answers to all three tests, and if sensation is severely affected all power of estimating weight may be lost. Although the patient may still appreciate the contact of the weights that are placed upon his hand, he may be totally unable to recognise their relation to one another, however the test may be applied.

In conclusion, we have found that—

1. The power of estimating the relative weight of two objects of the same size and shape is readily disturbed by cortical lesions.

2. Though the patient retains sensations of contact when the weight is placed in his hand all power of recognising the relative heaviness of the object has disappeared.

3. This faculty is equally disturbed in most cases whether the weights are placed on the supported or unsupported hand.

8.—APPRECIATION OF SIZE, SHAPE, AND FORM IN THREE DIMENSIONS.

To recognise size, shape, and form demands that the relation between two percepts should be correctly appreciated. In the case of the tests for size, we frankly ask our patients for the difference between two objects of the same shape. When testing for shape and form a relation is always implied between the test-object and something which the patient has experienced before.

In most cases when sensation is affected appreciation of size, shape, and form is lost; the patient usually complains that he has "not the least idea" of the shape or relative size of the test-objects. Although he insists that he "can feel them quite well," they convey no indication that they possess size, shape, or form. One of our patients recognised that the cone had a point because in his manipulations he pressed it into his hand; but he had no idea that it possessed any shape. This total abolition of the power to recognise size, shape, and form makes the defect peculiarly easy to discover even by the crudest tests. Thus, it is universally acknowledged that cortical lesions tend to destroy the power of recognising common objects, such as a knife, scissors, or coin placed in the hand, and our more accurately graded tests simply serve to confirm this general consensus of opinion.

This defective recognition is not in any way due to the paralysis produced by the cortical destruction; for in two cases where the movement of the hand was gravely affected size, shape, and form were perfectly recognised. When a test object is placed in the patient's hand it is of advantage if he can roll it between his fingers; but where the faculty of recognising these tests is maintained, even objects in three dimensions will be named correctly if the patient's fingers are closed over them passively.

The correct appreciation of size, shape, and form does not depend entirely on the recognition of posture, for it was perfectly retained in two cases, although postural recognition and the appreciation of passive movement were gravely affected. But in every case where the sense of posture was affected and we were unable at the same time to obtain a tactile threshold all recognition of size, shape, and form was abolished. Not that such recognition depends directly upon the state of tactile sensibility. The combined affection of the sense of posture and loss of the tactile threshold indicate simply that the defect produced by the lesion has reached a sufficient grade to destroy the power of recognising identity and difference. The appreciation of size, shape, and form, therefore, suffers like all tests which imply a relation.

9.—ROUGHNESS AND TEXTURE.

The power of appreciating roughness can be compared on the two halves of the body by means of the Graham Brown æsthesiometer. In this instrument one or more cylinders are projected to a measurable extent from a smooth metal surface and the patient says whether the instrument is smooth or rough when it is moved across some part, such as the hand.

In no case of quiescent cortical lesion was there any appreciable difference between the affected and normal parts. Not only could the patient experience no difference, but the extent to which the cylinder must be protruded to evoke a sensation of roughness was the same for the two sides. This stimulus is one which can be appreciated notwithstanding grave loss of sensibility produced by a cortical lesion. But in spite of this power to recognise the roughness or smoothness of the surface of the æsthesiometer all appreciation of texture may be lost. This test demands not only the immediate recognition that the object is rough or smooth, but the relation of that sensation to other percepts. Thus, although he may know that one surface is rough and another is smooth, he has no power of naming the substance by its texture. Cotton, silk, and velvet are all one to the affected hand, although readily distinguished on the normal side. When once this test has been applied the patients often complain that they have lost all idea of texture, saying, "I can feel it, but I have not the least idea what it is."

These two tests, both depending on the same sensory impulses, clearly illustrate the nature of the loss of sensibility produced by cortical lesions. The one depends upon the immediate appreciation of a smooth or rough stimulus. The other demands the correct relation of one group of precepts to another. The first is therefore maintained, whilst the second is destroyed by any cortical lesion which produces a measurable disturbance of sensibility.

10.—VIBRATION.

At lower levels of the nervous system a lesion frequently destroys all power of appreciating the vibrations of a tuning-fork. But we believe this never occurs from a stationary cortical lesion. Usually the patient can discover no difference in the sensations produced by the fork on the two halves of his body. Occasionally, however, he says it seems "plainer" or "stronger" on the normal than on the affected limb. If this is the case the vibration will be appreciated for a shorter period over the affected parts. The fork is set in motion and the patient is asked to say when he can no longer appreciate the vibration. It is then rapidly transferred to a similar spot on the normal limb and vibration may still be recognised for as much as 20 seconds longer. If this defect were greatly increased it is obvious that the power of recognising vibration would be abolished, but this never occurs from a pure cortical lesion. The vibration of a tuning fork seems to contain some sensory element which insures that it is appreciated even though the cortex is gravely affected. But the cortical lesion diminishes the "plainness" of the sensation and shortens its duration.

In some cases the vibration of the tuning fork not only seems "plainer," but is said to beat "faster" on the normal than on the affected limb. As this difference depends entirely on introspection a few patients only have noticed it, and we have avoided suggesting any change in the apparent relative rapidity on the two sides.

IV.—ANALYSIS OF THE LOSS OF SENSATION PRODUCED BY LESIONS OF THE OPTIC THALAMUS AND NEIGHBOURING PARTS.

In a previous section we have described the various forms of sensation which may be disturbed by lesions of the optic thalamus and its neighbourhood. Test by test we followed the loss of sensation, and showed that it varied in different cases within extreme limits. We shall now attempt to discover by analysis of these disturbances of sensation whether the impulses which pass away from the optic thalamus differ in their grouping from those which enter this organ from the mid-brain.

Since the optic thalamus is the terminal station for all secondary sensory paths, a lesion situated within its limits might destroy the receptive structures in which their impulses end; in such a case the loss of sensation would correspond to that produced by an equivalent lesion of the tracts of the mid-brain by which these impulses are conducted to the optic thalamus.

On the other hand, the lesion might leave this receptive mechanism intact but interfere with the paths that are streaming away to the cortex. In this case the sensory defect would reveal what elements of sensation pass to the cortex after they have been re-grouped in the thalamus.

1.—DISTURBANCE OF THE AFFERENT RECEPTIVE MECHANISM IN THE OPTIC THALAMUS.

In certain cases, which show the over-reaction to afferent stimuli and other signs indicative of a lesion of the optic thalamus, the loss of sensation is extremely gross. Not only

is sensibility for touch and temperature abolished, but even the threshold for painful stimuli may be raised. Pain, once appreciated, produces more discomfort on the affected half of the body; but in order that this appreciation may occur, the stimulus must be more intense than on the normal side. The strength of a prick, and the amount of pressure required to produce pain, are greater over the affected parts, although as soon as pain is produced the reaction is excessive. This loss of sensibility is probably due to interference with painful impulses either in the receptive portion of the optic thalamus, or as they still run in the secondary sensory paths which end in this junction.

We believe that in all cases which present the "*syndrome thalamique*," accompanied by loss of sensation so gross that the threshold is raised to affective stimuli, the receptive mechanism is affected; this seems to be situated mainly *in* the caudal portion of the lateral nucleus of the optic thalamus.

2.—DISTURBANCE OF SENSORY IMPULSES AS THEY PASS FROM THE OPTIC THALAMUS TO THE CORTEX.

In certain cases which show characteristic signs of a lesion of the optic thalamus the threshold to prick is identical on the two halves of the body and the readings of the pressure algometer may be actually lower on the affected side. The loss of appreciation of posture and passive movement may be severe, and the power of comparing two weights may be diminished, but the remaining forms of sensibility are less grossly affected than in that group of cases we have just considered.

Here we believe that the receptive mechanism is not affected to any material extent. The complete retention of painful sensibility shows that the impulses upon which it is based have been allowed to exert their full influence on the central organ where they are transformed into sensation. Moreover, the sensory elements are dissociated in ways which are unknown, until this level is reached; both the nature of the loss of sensation and the character of the sensibility which remains show that the afferent impulses must have been interrupted after they have undergone a fresh re-grouping at the thalamic junction. An analysis of these forms of dissociated sensation will therefore show the grouping of the impulses which pass away from the optic thalamus to act upon the sensory cortex.

It would seem that sensory impulses travel from the optic thalamus to the cortex in five groups. 1. Those concerned with the recognition of posture and passive movement. If these impulses are affected the power of discriminating weights on the unsupported hand may also be diminished. 2. Certain tactile elements; integrity of this group is necessary for the discrimination of weights placed on the fully supported hand. 3. Those impulses which underlie the appreciation of two points applied simultaneously (the compass test); on this group also depends the recognition of size, shape, and form in three dimensions. 4. Those which underlie the power of localising the situation of a stimulated spot. Recognition of the double nature of two points applied consecutively also depends on this group of impulses. 5. All thermal impulses are grouped together to underlie a scale of sensations with heat at the one end and cold at the other. At the level with which we are now dealing these impulses have already excited the affective centre and are passing away to the cortex.

V.—THEORETICAL CONCLUSIONS.

So far we have described in detail the effects which may follow lesions situated in different parts of the brain. In the present section we shall attempt, by analysis of these results, to present a coherent account of the mechanism of sensation.

The anatomical structure known as the optic thalamus is an extremely complex portion of the brain, and contains not only the terminal centre for certain aspects of sensations, but plays a threefold part in the fate of sensory impulses. 1. Firstly, it contains the termination of all secondary paths; here sensory impulses are grouped afresh and redistributed in two directions; on the one hand to the cortex cerebri, and on the other to the grey matter of the optic thalamus itself (*vide* section IV.). 2. Secondly, it contains a mass of grey matter, the essential organ of the thalamus, which forms the centre for certain fundamental elements of sensation. It is complementary to the sensory cortex and exercises different functions in the production of sensation. 3. Lastly, the lateral part of the optic thalamus is the organ through which the cortex can influence the essential thalamic centre, controlling and checking its activity. The excessive response to affective stimuli, so prominent a feature of lesions in this situation, is not due to irritation but to removal of cortical control.

Next we shall consider the nature of the activity of the sensory cortex. We shall show that it is concerned more particularly with discrimination and with the relation between two sensations, or between a sensation and its representation. It is essentially the organ by which attention can be concentrated on any part of the body.

Finally, we shall deal with the interaction of the cerebral cortex and the centre in the optic thalamus during the production of sensation.

1.—THE ESSENTIAL ACTIVITY OF THE THALAMIC CENTRE.

The most remarkable feature in that group of thalamic cases with which we have dealt in this work is not loss of sensation, but an excessive response to affective stimuli. This positive effect, an actual overloading of sensation with feeling tone, was present in all our 24 cases of this class; and, though emphasis has not been laid upon it as a characteristic feature, it has been observed by others in cases where the existence of a lesion in the lateral zone of the optic thalamus was confirmed by autopsy (Roussy [33], Edinger [8]). This excessive response may be accompanied by much or by little loss of sensation, but the extent of this loss bears no relation to the amount of the over-reaction to painful stimuli. But the characteristic thalamic response does not consist in an excessive reaction to painful stimuli only. In suitable cases we have shown that the response to pleasurable stimuli, such as warmth, is also greater on the affected side. Moreover, the manifestations of general mental states of pleasure and of pain may be more pronounced on the abnormal half of the body.

The pains and uncomfortable paræsthesiæ which occur in these cases have been explained by some observers as due to irritation. But this conventional hypothesis is insufficient to explain the observed facts in the clinical course of these cases. Moreover, we have pointed out that the response to pleasurable stimuli is also increased in some of these cases, a condition incompatible with the constant existence of an irritative lesion which evokes pain. Further, we have not found this peculiar over-response from lesions of other parts of the sensory path,[1] and the extreme rarity of such cases in the literature, compared with the overwhelming frequency of this over-response with the lesions of the optic thalamus, compels us to adopt some other explanation for its occurrence at this level of the nervous system.

Let us turn for a moment to the motor side of the nervous system where the effects produced by removal of control are more fully understood. It is well known that a lesion of the motor region of the cerebral cortex, or of the tracts which run from it to the spinal cord, produces not only loss of voluntary movement, but also a positive effect in the increased tone and rigidity of the affected limbs. This increase of tone, as Hughlings Jackson [13] pointed out in the Croonian lectures nearly 30 years ago, is not the direct effect of the destructive lesion, but is produced by the activity of subcortical centres released from control. He laid down the law that no destructive lesion can produce a positive effect directly. The activity of the cortex cerebri normally inhibits and controls subcortical motor centres, and the destructive lesion sets these centres free to display their powers unchecked. Loss of voluntary power is consequently associated with tonic over-action and an increased reflex discharge in response to afferent impulses.

We believe that an exactly similar condition is revealed on

[1] Spontaneous pains associated with over-sensitiveness to prick or other stimuli have been described as a consequence of lesions of the central nervous system at other parts of the sensory path, but few of these cases will stand criticism. For example, in the case published by Raymond and Rose [30] as a lesion of the pons varolii the authors themselves admit the possibility of multiple lesions, and the presence of choreic and athetoid movements points in all probability to affection of the optic thalamus. Raymond and Français [29] recorded a pontine case in which pains and "hyperæsthesia" to prick were present, but the position of the lesion was not determined by autopsy. In Mann's case [20] there was merely persistent unilateral pain, and Mann himself recognised that this was accompanied by "hypæsthesia" and not by "hyperæsthesia," as in Edinger's case of thalamic disease with which he contrasted it.

the sensory side of the nervous system by cases of thalamic disease accompanied by an excessive response to peripheral stimuli. We know that paths run, not only from the optic thalamus to the cortex, but from the cortex to the thalamus, and they have been shown ([23] [4] [36]) to terminate in its lateral zone, the very region affected in cases that have exhibited the "syndrome thalamique." But since these paths come from all parts of the cortex to impinge upon the optic thalamus the functions they exercise cannot be removed by partial destruction of the cerebral hemispheres; cortical lesions produce no thalamic over-response to affective stimuli.

The only function which can be ascribed to these cortical thalamic paths is that through them the cortex controls, in some way, the activity of the thalamus. If this view is correct, lesions which interrupt these paths, but leave intact the main substance of the optic thalamus, must lead to a permanent over-activity of functions exercised by that organ. Any afferent impulses which are capable of exciting this part of the brain will act on an uncontrolled centre and must, consequently, evoke an excessive effect.

We believe that the essential organ of the optic thalamus is the centre of consciousness for certain elements of sensation. It responds to all stimuli capable of evoking either pleasure and pain, or consciousness of a change in state. The feeling-tone of somatic or visceral sensation is the product of thalamic activity, and the fact that a sensation is devoid of feeling-tone shows that the impulses which underlie its production make no thalamic appeal. The functions of this organ are influenced by the coincident activity of the cortical centres, and this control is effected by means of paths from the cortex to the thalamus which probably end in its lateral nucleus. Injury in this region sets free the thalamic centre from control, and it can therefore react without restraint to all stimuli capable of arousing affective states. Since, however, most stimuli which act upon the body in daily life are noxious and so contain a disagreeable element, most sensations experienced by the patient with a lesion of the optic thalamus are painful. This is particularly the case when sensation is so gravely diminished that stimuli of great intensity only can reach consciousness. The occurrence of spontaneous pains and the painful paræsthesiæ of the affected half of the body, so constant a feature of these cases, are due to the uncontrolled activity of this centre through which painful stimuli evoke a disagreeable sensation.

2.—THE NATURE OF THE SENSORY ACTIVITY OF THE CORTEX.

In a previous section we have described the results produced by a cortical lesion upon a series of measured sensory tests. Let us now analyse these defects in the hope that thereby we may learn the part played by the cortex in that response to an external stimulus we call a sensation.

Afferent impulses on their way from the periphery to the cortex pay toll first of all to the unconscious coördinating mechanisms of the spinal cord and the cerebellum. Then, after being regrouped at the thalamic junction, they act upon two terminal centres. One of these, the essential organ of the optic thalamus, responds to all those elements which can evoke consciousness of an internal change in state, more particularly pleasure and discomfort. Sensory impulses then pass by way of the internal capsule to act upon the cortex, and these are the afferent materials out of which the cortex manufactures the forms of sensation with which it is concerned.

We know the nature of these impulses as they travel through the capsule to the cortex; it is revealed by those cases of thalamic and capsular disease in which the loss of sensation is due to interference with paths which pass from the optic thalamus to the sensory cortex. The dissociations of sensibility which can occur under such conditions show that, after exciting the essential centre of the optic thalamus, sensory impulses pass on in five main groups to be distributed to the cortex: 1. Those which underlie postural recognition and the appreciation of passive movement. Upon this group depends the secondary faculty of judging the difference or identity of two weights placed on the unsupported hands. 2. Impulses which underlie the recognition of tactile differences or the power of appreciating those qualities of touch other than contact and roughness. To this group we owe the faculty of recognising the increase or diminution in weight of a test-object and of distinguishing the difference between two weights placed on the supported hand. 3. Those upon which depend spacial discrimination (compass-points applied simultaneously) and its allied faculty, the recognition of size and shape. 4. Those impulses which enable the patient to recognise the spot stimulated (localisation). They carry with them the power of appreciating the double nature of two points applied to the surface one after the other. 5. Thermal impulses. On this group depends the possibility of recognising those degrees of temperature which necessitate a comparison with the consequences of some previous thermal sensation. Such are the afferent materials out of which the cortex manufactures those forms of sensation for which it is responsible.

The power of estimating the relative warmth or coldness of two stimuli suffers when thermal sensibility is affected by a cortical lesion. The power of discriminating the relative coolness of two cold stimuli and the relative warmth of two hot tubes is diminished, provided two temperatures are chosen which do not appeal differently to the thalamic sensory centre. Thus even the faculty of appreciating the relative intensity of two temperatures on the same side of the scale is disturbed, although both may be named correctly. But these stimuli contain elements capable of rousing the activity of the essential thalamic centre. The tests for the recognition of posture, of passive movement, spacial discrimination (compasses), and the locality of the stimulated spot contain no such elements, and it is these aspects of sensation that suffer most profoundly in consequence of a lesion of the sensory cortex. Postural recognition and the appreciation of passive movements are usually grossly affected. The power of localising the stimulated spot is less frequently disturbed, but may be abolished. These two faculties are independent of one another and may be affected separately. Moreover, a disturbance of localisation caused by a lesion of the cortex is not due to coincident uncertainty of tactile sensibility, for it is equally demonstrable when the stimulus is a prick to which the patient responds on every occasion.

When dealing with the arrangement of the sensory impulses which pass through the internal capsule to be distributed to the cortex, we showed that the power of estimating weight, size, shape, and form in three dimensions depends on the integrity of several separate groups. Thus, the appreciation of difference between two weights placed in the unsupported hand demands perfect postural recognition. The faculty of estimating weights placed consecutively on the supported hand depends on the integrity of tactile sensibility. Such dissociation is impossible with lesions of the cortex, for we are no longer dealing with a disturbance of sensory impulses, but with the difficulty of recognising the relation between two percepts. The patient generally gives up all attempts at appreciation, saying he has "no idea" of the shape, form, or relative size and weight of the test-object.

The tests for the appreciation of roughness and of texture demonstrate clearly the part played by the cortex in sensation. With Graham Brown's æsthesiometer the threshold is identical on both hands; in every case the amount of protrusion necessary to make the flat surface of the instrument seem rough is the same on the two sides. In this test the patient has to determine solely whether the sensation is one of roughness or smoothness. But as soon as he is asked to correlate these sensations and combine them with those of touch, as in the tests for the appreciation of texture, he fails entirely.

Evidently one of the faculties which we owe to cortical activity is the power of relating one sensation to another, whether they arise simultaneously or consecutively. Recognition of weight, size, shape, form, and texture depends entirely on this faculty. Such tests consequently reveal the grossest defects whenever a cortical lesion produces any considerable influence upon sensibility. A little consideration shows that loss of this faculty of relation is at the bottom of the diminished appreciation of posture and passive movement which constantly forms one of the gravest defects produced by lesions of the cortex. For it would be impossible to discover the position of any part of the body unless the immediate postural sensations were related to something that had preceded them. A direct perception of posture, analogous to that of roughness, is impossible; in every case the new position of the limb is relative to some

previous posture. At any moment we can become conscious of the position of any part of our bodies, and although such postural recognition is not constantly in the central field of attention it always forms the measure against which we judge subsequent change. This is peculiarly the case with the appreciation of passive movement. When we sit immobile and imagine our fingers touching some object on the table many of us see at once the picture of an outstretched arm; the only image in consciousness is a visual one. Now in cases where all power of recognising posture is lost this visual image remains unchanged, and it cannot therefore be the standard to which we refer alterations in posture. Place the patient's affected arm in front of him on the bed, allowing him to see the position in which it lies; close his eyes, and in most cases he will see a mental picture of his hand. Then change its position whilst his eyes remain closed and he will continue to see a picture of the hand in its old position. Moreover, if localisation is not affected he will name correctly the spot stimulated, but will refer it to the position in which he visualises the hand. The visual image of the limb remains intact, although all power of appreciating changes in position is abolished. It is evident, therefore, that the standard resulting from previous postures and movements, to which immediate reference is made when a fresh position is recognised, cannot be a visual image.

Every recognisable change enters into consciousness already charged with its relation to something that has gone before, just as on a taxi-meter the distance is presented to us already transformed into shillings and pence. So the final product of the tests for the appreciation of posture or passive movement rises into consciousness as a measured postural change.

For this combined standard, against which all subsequent changes of posture are measured before they enter consciousness, we propose the word "schema." By means of perpetual alterations in position we are always building up a postural model of ourselves which constantly changes. Every new posture or movement is recorded on this plastic schema, and the activity of the cortex brings every fresh group of sensations evoked by altered posture into relation with it. Immediate postural recognition follows as soon as the relation is complete.

In the same way recognition of the locality of the stimulated spot demands the reference to another "schema." For a patient may be able to name correctly and indicate on a diagram, or on another person's hand, the exact position of the spot touched or pricked, and yet be ignorant of the position in space of the limb upon which it lies.

It is to the existence of these "schemata" that we owe the power of projecting our recognition of posture, movement, and locality beyond the limits of our own bodies to the end of some instrument held in the hand. Without them we could not probe with a stick, nor use a spoon unless our eyes were fixed upon the plate. Anything which participates in the conscious movement of our bodies is added to the model of ourselves and becomes part of these schemata: a woman's power of localisation may extend to the feather in her hat. Thus, it is evident that among the various functions of cortical activity which imply a relation, the act of comparison may be of different grades in the hierarchy of consciousness.

Evidently a lesion of the cortex produces an effect upon sensation of a different order from that found at any lower level of the nervous system. All those defects which may occur when a normal person is under examination with psycho-physical tests are present in a grossly exaggerated form. Those defects which we ordinarily attribute to want of attention are raised to a degree unknown in the normal human being. But the patient's power of general attention has not been lowered in such cases as those we have cited in this paper. Records from the limbs of the sound side show that the phenomena of defective attention are confined to the abnormal parts. A portion only of the patient has, as it were, become untrustworthy.

To sum up, we believe that the cerebral cortex is the organ by which we are able to focus attention upon the changes evoked by sensory impulses. A pure cortical lesion which is not advancing or causing periodic discharges will change the sensibility of the affected parts in such a way that the patient's answers appear to be untrustworthy. Such diminished power of attention makes the estimation of a threshold in many cases impossible. Uncertainty of response destroys all power of comparing one set of impressions with another and so prevents discrimination. But in addition to its function as an organ of local attention the sensory cortex is also the storehouse of past impressions. These may rise into consciousness as images, but more often, as in the case of spacial impressions, remain outside central consciousness. Here they form organised models of ourselves which may be termed "schemata." Such schemata modify the impression produced by incoming sensory impulses in such a way that the final sensations of position, and of locality, rise into consciousness charged with a relation to something that has happened before. Destruction of such "schemata" by a lesion of the cortex renders impossible all recognition of posture or of the locality of a stimulated spot in the affected part of the body.

3.—THE INTER-RELATION OF THE OPTIC THALAMUS AND THE CORTEX IN THE PRODUCTION OF SENSATION.

In daily life all stimuli excite more or less both thalamic and cortical centres, for most unselected sensations contain both affective and discriminative elements. But amongst the tests we have employed in sensory analysis some appeal almost entirely to the one or other centre. The test for recognition of posture, as carried out by us, is purely discriminative; whilst the pain produced by squeezing the testicle, or to a less degree by the pressure-algometer, appeals almost exclusively to the more affective centre.

Sensory impulses arriving at the optic thalamus are re-grouped in such a way that they can act upon both its essential centre and the sensory cortex. The essential organ of the thalamus is excited to "affective activity" by certain impulses and refuses to react to those which underlie the purely discriminative aspects of sensation. These pass on to influence the cortical centres where they are readily accepted. In a similar way the primary centres of the cortex cannot receive those components which underlie feeling-tone; in this direction they are completely blocked.

It has long been recognised that sensations are endowed with feeling-tone to different degrees. In those which underlie postural appreciation this quality is entirely absent, whilst visceral sensations are, in some instances, little more than a change in a general feeling-tone; one set of impulses appeals almost exclusively to the cortical centre, the other to that of the optic thalamus. All thermal stimuli, however, make a double appeal. Every sensation of heat or cold is either comfortable or uncomfortable; the only entirely indifferent temperature is one that is neither hot nor cold.

In the same way most unselected tactile stimuli appeal both to the sensory cortex and to the optic thalamus. For not only is a touch always related to, and distinguished from, something that has gone before it, but we have shown that contact, especially of an object moving over hair-clad parts, is capable of exciting thalamic activity. Vibrations of the tuning-fork also make a double appeal, for when the cortical paths are cut the amplitude of the vibration must be greater in order that they may be appreciated; on the other hand, the vibratory effect may be stronger on the abnormal side in those thalamic cases where the affective response is excessive.

But these two centres of consciousness are not co-equal and independent. Under normal conditions the activity of the thalamic centre, though of a different nature, is dominated by that of the cortex. When we examine the sensation normally produced by a prick we recognise that the pain develops slowly and lasts a considerable time after the stimulus has ceased. Moreover, the same intensity of stimulation will produce a different effect on the same spot on different occasions. A long, latent period, persistence, and want of uniformity are characteristic of all painful sensations. This is seen in an exaggerated form in cases where the thalamic centre has been freed from control. The response to prick is slow, but persists long after the stimulus has ceased. Moreover, the reaction when it occurs tends to be explosive; it is as if a spark had fired a magazine and the consequences were not commensurate with the cause.

On the contrary, the sensations normally produced by moderate tactile stimuli are characterised by a short latent period, and disappear almost immediately on the cessation of

the stimulus. A lesion of the sensory cortex disturbs both these characteristics. Tactile sensations became uncertain and incalculable, and no threshold can be obtained; persistence and hallucinations mar the uniformity of the records.

Now we have shown that the sensory cortex is the organ by which attention can be concentrated on any part of the body that is stimulated. The focus of attention is arrested by the changes produced by cortical activity at any one spot. These are sorted out and brought into relation with other sensory processes, past or present. Then the focus of attention sweeps on, attracted by some other object.

All stimuli which appeal to the thalamic centre have a high threshold. They must reach a high intensity before they can enter consciousness, but once they have risen above the threshold they tend to produce a change of excessive amount and duration, and this it is the business of the cortical mechanism to control. The low intensity of the stimuli that can arouse the sensory cortex, and its quick reaction-period, enable it to control the activity of the cumbersome mechanism of the thalamic centre.

Our view of the sensory mechanism put forward in this paper explains many of the facts already recognised both by psychologists and clinicians. It enables us to understand how integration can occur at all afferent levels of the nervous system, and makes development possible even in the individual. The aim of human evolution is the domination of feeling and instinct by discriminative mental activities. This struggle on the highest plane of mental life is begun at the lowest afferent level, and the issue becomes more clearly defined the nearer sensory impulses approach the field of consciousness.

SALVARSAN IN SYPHILIS.

BY WILLMOTT EVANS, B.S., B SC. LOND, F.R.C.S. ENG.,
SURGEON TO THE ROYAL FREE HOSPITAL, LONDON.

THE reception of salvarsan by the medical profession in this country has been by no means uniform. While many favourable results have indeed been reported, it is also the fact that many expressions of opinion have appeared during the last few months in the medical journals adverse to the utility of salvarsan in the treatment of syphilis. It is true that for the most part these have come from those who have had but little practical experience of the method; nevertheless they have received, and have deservedly received, attention owing to the high position occupied by their writers. In these circumstances I feel it to be almost a duty to bear witness to the good results which I have seen follow the use of this drug, and that I should state that so far no harmful effects have come under my notice. Whether salvarsan will fulfil all the great expectations which were entertained on its first publication is doubtful, but that it is a drug strikingly effective in the treatment of syphilis I am fully persuaded.

This paper is intended to be nothing more than a preliminary note on the subject, for I hope later to publish a fuller account of my experiences with salvarsan, but my object in bringing forward the matter now is to show that if care be taken in the selection of the cases and the drug be administered cautiously the results obtained are extremely good, and in some cases at least have proved to be unattainable by other means.

Before the drug was put on the market Professor Ehrlich, at the request of the Editor of THE LANCET, very kindly sent me a supply of ampoules of "606" for the purpose of testing its value, and from that time to the present I have used it. My aim in its employment was to observe carefully the results of its use in comparatively few cases rather than to administer it to every case of syphilis seen by me. Also, in order to test the value of the drug with care, I did not inject any cases except those which gave a positive Wassermann reaction in addition to giving clinical signs of the disease. I rejected some cases in which the reaction was negative, even though clinically the diagnosis of syphilis was extremely probable or even practically certain, because I wished to be sure that the case was certainly syphilitic. I have employed the drug both in primary, secondary, and tertiary manifestations of the disease, and also in some cases exhibiting those later manifestations of syphilis which are often called parasyphilitic but are better called quaternary. Instead of giving particulars of the whole series, I think that I can more clearly present the effect of the treatment, and that the conclusions may prove of more value to others if I state simply the results which I have obtained.

Dose.—In my early cases I employed 0·45 gramme, but later I employed 0·5 and now 0·6 gramme. It has appeared to me that the improvement in the cases has been more rapidly shown with the larger dose, and I have not seen harm result from it in any case. It is possible that later the dose may have to be somewhat increased, but as to that time will show.

Mode of administration.—In my early cases I administered the drug by an intramuscular injection, and though it is an effective method it certainly gives rise to a good deal of pain for a few hours. This pain can be, in great part, controlled by a hypodermic injection of a quarter of a grain of morphine, and I have found it a good plan to give this morphine injection ten minutes or a quarter of an hour before the injection of the "606." Later I injected the drug intermuscularly in the following manner. The posterior fold of

the axilla is picked up between the finger and thumb an inch or two below the level of the angle of the scapula, and as this fold is formed by the latissimus dorsi that muscle will be held. The needle of the syringe is then passed deep to the muscle, so that it lies between the latissimus dorsi and the serratus posticus inferior. The injection of the preparation into this space causes much less pain than when the injection is intramuscular, for there is much less tension, and though the pain is sometimes troublesome, yet it is readily controlled by a hypodermic injection of morphine.

Mode of preparation for an intramuscular or intermuscular injection.—The method of preparation I have employed has been practically that which was shown me by Mr. J. E. R. McDonagh. The powder is rubbed up with a solution of sodium hydrate and then treated with acetic acid until the liquid is still just acid and then a little solution of sodium hydrate is added until it is just alkaline. The syringe used has a glass barrel and a solid metal piston. It was used fairly warm for two reasons, mainly not to chill the liquid to be injected, but partly also because when warm the piston fits more closely. The liquid is drawn into the syringe and then a little warm water is used to wash out the mortar, and that is also drawn into the syringe. Prepared in this way the bulk of the liquid is not great; it varies between 8 and 12 c.c., 9 or 10 being about the average—that is to say, it measures between two and three teaspoonfuls. The fluid is injected gently and the pain is not very great.

In the intravenous injection a weak alkaline solution is made as follows: A bottle is taken with divisions showing 50 c.c. About 100 c.c. of sterile water or saline solution are placed in the flask which contains a number of glass balls; the salvarsan (0·6 gramme) is then added and about 18 or 20 minims of 15 per cent. solution of sodium hydrate are added until a clear solution results. The bottle is shaken while the alkali is being added and the balls assist the solution of the powder. The bulk of the liquid is then made up to 300 c.c., which is the amount to be administered. A sharp needle is attached to a piece of rubber tubing and to the other end of that is a glass funnel. The funnel and tubing are filled with saline solution at a temperature of about 105° F., and the skin over the front of one elbow is painted with a 3 per cent. alcoholic solution of iodine. By means of a bandage tied round the upper arm the veins are rendered distinct, and the needle is inserted into one of the veins in front of the elbow, either the median cephalic or the median basilic, and some of the saline solution is allowed to run in. Then some layers of sterile gauze are placed in the mouth of the funnel for the purpose of filtering the solution which is poured into the funnel. The time taken by the 300 c.c. in entering the vein should, I think, be between 20 minutes and half an hour. When all the solution has been injected, it is well to let a little saline solution flow through the needle, so that when the needle is removed no salvarsan is left in the tissues. Some precautions are of great importance. All the apparatus employed must have been carefully sterilised. The solution should not be too cool, it is best to have it a few degrees over 100°, otherwise it may chill the patient and perhaps cause a shivering fit. The flask is easily warmed by standing it in hot water.

Wassermann's test.—As I have mentioned above, I have not injected any case with "606" unless and until it has given a positive Wassermann test. In some of the cases the fact that the test was negative was probably due to previous administration of mercury; nevertheless, I did not inject any case until the Wassermann test became positive. I have found that it may take between two or three months for a Wassermann test to become positive after it has been negative from the administration of mercury. I am aware that it has been stated that mercury does not interfere with the Wassermann test, but that has not been my experience.

Harmful results.—I have had no results which could be called harmful. In no instance has an abscess formed locally, though in one case a little fluid collected at the site of injection, but the contents were quite clear. In no case have any ocular symptoms resulted. I cannot help thinking that in most of the cases in which harm has resulted there has been some fault in technique. In some instances apparently the solution has been injected into the vein without filtration, so that the risk of embolism has been run. The greatest care is required and must be used.

Stage of the disease.—The drug has proved efficacious in all stages of syphilis—in the primary, secondary, and tertiary stages, and also in the parasyphilides. I think the most rapid results followed the treatment when the disease was in the tertiary stage. The manifestations of the secondary stage were distinctly less rapidly affected, possibly because, as Ehrlich has suggested, the drug cannot affect an area where the vessels are thrombosed. I need not describe in detail any cases in which the manifestations were those common in syphilis, but there are a few that deserve special mention.

In the first case which I injected the patient was a young woman, who had numerous manifestations of syphilis probably congenital in origin. She had on the leg a deep gummatous ulcer, measuring some 2½ inches in length and an inch in breadth. The depth also was about an inch. In addition she had a gummatous deposit in the left orbit causing some proptosis; there were marked atrophy of the disc and little more than the perception of light. At first I had some hesitation about using the drug in a case where the eye was already damaged, but it was clear that the loss of sight of the left eye was so serious that no real harm could be done. As a result of the injection the proptosis almost disappeared and curiously the vision improved markedly. The ulcer on the leg healed, though slowly. A few weeks later slight ulceration reappeared in the scar of the leg, but it only lasted for a short time and it again healed and has not broken down since, and no syphilitic manifestation has appeared subsequently, although nearly two years have elapsed since the injection. In this case the patient had been very thoroughly treated with mercury by one of my colleagues, but without effect.

In one case, where several nodules existed on the skull and much thickening of the left femur was present, rapid recovery followed the use of salvarsan, and, further, an old ununited fracture of the tibia united a few weeks after the injection.

In another case a woman was injected during the third month of pregnancy; labour took place at term, and the child was born perfectly healthy, and neither child nor mother has since exhibited any manifestations of the disease. In fact, the child is above the average in well-being.

In several cases of syphilis of the spinal cord and brain the improvement was marked, though the first signs of improvement were slow in appearing.

I used salvarsan in a fairly early case of general paralysis of the insane, but no noticeable improvement occurred. I am inclined to think that for intracranial syphilis the intramuscular method of injection is better than the intravenous, for the introduction of the drug into the circulation is less rapid. In most cases, however, I have no doubt that the intravenous injection is far preferable to any other mode of administration, but I repeat once more that it needs much care.

Recurrences.—So far I have had no case in which I have found it necessary to repeat the dose; doubtless in time such cases will occur to me as they have occurred to others.

Conclusions.—Judging merely from my experience of the cases treated by me, I can say that salvarsan is a rapid, safe, and effective treatment of syphilis. That it affords a permanent cure it is as yet impossible to say, but from our present knowledge it appears to me the most satisfactory method of treatment.

Harley-street, W.

ON THE

PRACTICAL RESULTS OF THE RECENT ADVANCES IN THE DIAGNOSIS AND TREATMENT OF SYPHILIS.[1]

BY J. H. SEQUEIRA, M.D. LOND., F.R.C.P. LOND., F.R.C.S. ENG.,

PHYSICIAN TO THE SKIN DEPARTMENT OF, AND LECTURER ON DERMATOLOGY AT, THE LONDON HOSPITAL; CONSULTING DERMATOLOGIST TO THE RADIUM INSTITUTE.

I WOULD, in the first place, insist upon the importance of a wide recognition of the advances which have been made in the diagnosis and in the pathogeny of syphilis as well as in its treatment. The work of Roux and Metchnikoff, of Neisser, Ehrlich, and many others has brought to fruition the epoch-marking discovery of the spirochæta pallida by Schaudinn, a discovery not less important to the community

[1] Abstract of a paper read before the Plymouth Medical Society on Dec. 16th, 1911. The paper was illustrated by photographs and coloured drawings of patients.

than the discovery of the bacillus tuberculosis by Robert Koch.

Although Metchnikoff and Roux had shown that syphilis could be produced experimentally in the chimpanzee shortly before Schaudinn and Hoffman published their discovery of the spirochæta pallida, that discovery made it possible to extend and develop the lines of experiment. Neisser has shown that the spirochætæ leave the site of infection very soon after inoculation, and only by excising the primary lesion within 12 hours was he able to prevent general infection. Levaditi and others have demonstrated that the organisms spread along the lymphatics and the perivascular spaces and also by the blood stream. By the inoculation of animals with the discharge from the primary sore it is easy to demonstrate its infectivity, and, as we should have expected on clinical grounds, mucous patches and condylomata are infectious in a high degree. On clinical grounds, however, it has long been held that tertiary lesions are not infectious, but Finger and Landsteiner were able to infect a monkey from the lesions of a patient whose primary sore dated back 12 years. Neisser and others have confirmed these observations. These positive findings are of great practical importance, as they show that the spirochætæ are present in tertiary lesions.

It has been found very difficult to infect the ape with the blood of a syphilitic subject, but the semen has been shown to convey the infection, while the secretion of the mammary gland of a syphilitic nursing woman does not. To Neisser we owe the demonstration of the infectivity of the nasal discharge of infants suffering from congenital syphilis.

Diagnosis.

The demonstration of the spirochæta pallida is best performed by dark background illumination. There is now no need to apply elaborate methods of staining. [The technique of dark background illumination was here explained and photographs of preparations made by Dr. James McIntosh were demonstrated. The importance of a sufficiently intense illumination was insisted upon, the examination being most conveniently made with a one-sixth power and a high eyepiece.] Some experience is necessary to distinguish the spirochæta of syphilis from some other spirillar organisms, but with a little training the examination can be made in a few minutes. The most satisfactory conditions for a successful examination are the removal of a small quantity of the serum from an untreated chancre, obtained by pressing the part after cleansing the surface with saline. The spirochætæ can also be demonstrated in the exudation from condylomata, mucous patches, and from ulcerating secondary lesions. In the other secondary eruptions the method is of little practical value.

While every practitioner cannot be expected to have the necessary knowledge for making these examinations, it ought not to be beyond the range of practical politics for the health authorities in every town at least to be able to give the required assistance to the practitioner, just as is done in the recognition of the Klebs-Löffler bacillus in diphtheria. The practical importance of the early recognition of the disease will be more apparent on consideration of some of the later observations. It will simply be necessary here to remark that as far as possible all cases should be treated in the primary stage.

The Indian ink method of Burri for the demonstration of the spirochæta has the advantage of simplicity. A drop of the serum from a chancre being mixed with a drop of sterilised Günther-Wagner Indian ink is examined after drying with an oil-immersion lens. Owing to the differences in the thickness of the film Dr. McIntosh and Dr. Paul Fildes consider that this method is open to objection because a thin film makes the parasites appear thicker, and in a thick film they appear thinner, and, moreover, the characteristic movements of the spirochætæ as observed with dark background illumination are absent.

The influence of salvarsan on the spirochætæ in a primary sore is remarkable. It is common to find the serum of a chancre in which spirochætæ were in large numbers entirely free from parasites 8 to 12 hours after injection. Such a result is of the highest importance in preventing the spread of the disease.

The Wassermann Reaction.

[The technique of the Wassermann reaction was here described, and the explanations which have been given of its meaning were considered. Dr. Sequeira remarked upon the increased accuracy which had been developed by the quantitative observations of Boas, observations which had been carried out in a number of cases under his care by Dr. McIntosh and Dr. Fildes in the bacteriological department of the London Hospital. The practical value of the reaction was unquestionable provided the principles laid down by Wassermann, Neisser, and Bruck were observed.]

In primary syphilis the utility of the Wassermann reaction is usually underestimated. With the more exact methods now in use McIntosh and Fildes were able to obtain a positive reaction in 24 out of 25 cases. Taking a large number of observations, Boas found that a positive reaction may be expected in 75 per cent. of primary cases. A positive reaction may be obtained as early as five weeks after *infection*, and is usually present nine weeks after infection. (N.B. This is the time after exposure to infection and not after the appearance of the chancre.) In secondary syphilis a positive reaction is obtained in 90 per cent. of the cases examined, but Boas with his more careful technique did not get a single negative result in 250 cases. In tertiary syphilis 63 per cent. of the cases give a positive reaction, but it must be remembered here that treatment must be taken into account. In congenital syphilis a positive reaction is practically constant.

The simple recapitulation of these facts is sufficient to demonstrate the value of the test, and we have only to remember that there are two other conditions occurring in this country in which a positive Wassermann reaction may be obtained, and those are leprosy, more commonly in the nodular than in the anæsthetic variety, and a transitory reaction in about 5 per cent. of the cases of scarlet fever.

The value of the Wassermann reaction is constantly brought home to those practising in dermatology, and especially in the differential diagnosis between syphilitic and tuberculous eruptions. It should be possible to make such arrangements with local authorities that a practitioner could obtain anywhere the assistance given by this examination. The blood is easily taken and can be sent through the post in suitable vessels, and it is of as much importance to the community that syphilis should be diagnosed early and correctly as typhoid fever. No difficulties are in the way of the practitioner in obtaining a Widal examination, and there should be equal facilities for the estimation of the Wassermann reaction. In some of our more enlightened colonies the Wassermann reaction can already be obtained without difficulty by any practitioner having a doubtful case.

The Influence of Treatment on the Wassermann Reaction.

Mercury.—Nearly every case of syphilis is influenced by mercury. A positive Wassermann reaction may be expected to become negative in a definite proportion of cases after one course of treatment, and the percentage rapidly rises with repeated courses. Harrison's statistics are most important and illustrative in this connexion. They are clearly shown in the following table:—

Effect of Courses of Lambkin's Cream.

After 1 course	83	per cent.	still positive.
,, 2 courses	77	,,	,,
,, 3 ,, ...	64	,,	,,
,, 8 or more courses	21	,,	,,

That is to say, that after eight courses 21 per cent. showed by the Wassermann test that they were still syphilitic.

McIntosh found as the result of the examination of 160 cases treated by Hutchinson's pills, that after one year's treatment a positive reaction was obtained in 92 per cent.; after two years' treatment in 54 per cent.; and after more than two years' treatment in 30 yer cent.

The earlier and the more energetic the treatment the greater proportion of negative reactions. This last point is of the highest practical importance and should certainly lead to the abandonment of the old practice of waiting for the development of the secondary symptoms. We cannot start our treatment too early.

Iodide of potassium.—Though it has not received so much attention it has been shown that iodide of potassium has a definite effect upon the Wassermann reaction, but not in all cases.

Arsenic.—In the form of Fowler's solution administered orally Boas was able to obtain a negative reaction in 6 out of 11 cases.

The effects of the Wassermann reaction in the more recent use of arsenic in the form of salvarsan have been very closely studied. McIntosh and Fildes have carefully followed a

number of cases treated at the London Hospital, and they arrived at the following conclusions.[2] Intramuscular and subcutaneous injections were first used. In primary syphilis no case failed to become negative, the average time being five weeks. In secondary syphilis one-third of the cases failed to become negative. Where a negative result was obtained the average time was 8 weeks. In tertiary syphilis only one case became negative. It is, therefore, obvious that the longer the infection the more difficult it is to influence the Wassermann reaction by treatment. With intravenous and intramuscular injections combined, no case of secondary syphilis failed to become negative. The average time was 6½ weeks. In tertiary syphilis nearly one half of the cases gave a negative reaction. There is no doubt, therefore, that the intravenous method is more effective than the intramuscular or subcutaneous. As large doses as are compatible with safety are indicated as early as the diagnosis is made, with a view to preventing the development of a strain of spirochætæ resistant to the drug.

Administration of Salvarsan.

[The administration of salvarsan was next considered, and the apparatus in use at the London Hospital, devised by Dr. McIntosh and Dr. Fildes, was demonstrated.]

In the McIntosh and Fildes apparatus the injection is introduced by air-pressure, the pressure being supplied by a rubber pump connected with a bottle containing the solution. The air from the pump is passed through sterile cotton wool. The apparatus is portable, and all its parts can be sterilised and brought to the bedside of the patient in a sterile condition. It is important to observe care in the preparation of the solution, especially in its neutralisation with alkali, its freedom from undissolved particles, and its proper dilution, several of the fatalities following its use being due to the absence of these precautions. The directions given by the makers should be followed with scrupulous attention.

It has now been shown possible to eliminate almost all the untoward after-effects of the intravenous injection—viz., shivering, pyrexia, and vomiting—by the use of a saline made from freshly distilled water. It is believed that ordinary distilled water contains matter, whether bacterial or other, which is responsible for these immediate after-effects. Pyrexia, shivering, &c., have been produced in my clinic in non-syphilitic patients by the injection of 300 c.c. of normal saline prepared in the usual way. These observations have been made by my former clinical assistant Mr. H. Dearden in conjunction with Dr. McIntosh and Dr. Fildes. It is now the exception with the use of saline made with redistilled water to see any rigors, pyrexia, or vomiting after the intravenous injection of salvarsan.

[The fatalities observed after the use of salvarsan were commented upon, and it was shown that a number of them were undoubtedly due to faulty technique, e.g.: (1) failure to neutralise the highly toxic acid solution; (2) insufficient dilution; (3) sepsis leading to thrombosis and embolism; and (4) failure to insist upon patients being kept at rest after the injections. In other cases the drug had been used in unsuitable cases, moribund infants, general paralysis, extreme cachexia, and grave non-syphilitic visceral disease.]

It can be stated on the authority of the agents of the manufacturers that about a million doses of salvarsan have been sold, and presuming that half a million subjects have received injections, it becomes obvious that the mortality cannot be so high as certain authors suggest. Naturally all the fatal cases have not come to light, but supposing even 50 fatalities have occurred the mortality will not be more than 0·01 per cent., and this with a potent drug requiring a careful technique and selection of cases still in the experimental stage cannot be considered high.

The important question of the permanence of the results cannot be settled yet. Definite clinical relapses undoubtedly follow the use of salvarsan. In one case at the London Hospital, after apparent cure, the patient had a return to a positive Wassermann reaction after 36 weeks, in another after 16 weeks. During the period of observation I have not interfered with the effect of the new remedy by the administration of mercury for fear of confusing the issue. There can of course be no reason why mercury should not be given to supplement the effect of the salvarsan, and it may perhaps be ultimately proved that this is the best method of treating syphilis, and it is now advocated by many eminent authorities.

Conclusions.

My own conclusions I may summarise as follows:—

1. The early diagnosis of syphilis is of the utmost importance (*a*) to prevent the spread of the infection, and (*b*) for efficient treatment. Treatment should be begun in the primary stage. There should be no waiting for secondaries.

2. A doubtful chancre should be examined for spirochætæ. The dark background illumination method affords a reliable means provided the lesion has been untreated. Such an examination ought to be within the reach of all patients in the towns and might be arranged for by the health officer.

3. The Wassermann reaction is of the highest utility in the diagnosis of secondary and tertiary eruptions. If carried out by the improved technique practically every secondary case gives a positive reaction. The reaction is also of value in determining and estimating the effect of treatment. The Wassermann reaction ought to be as much within the reach of every patient as is the Widal reaction or the examination of diphtheritic swabs.

4. Treatment by mercury is undoubtedly efficacious. Nearly every case is influenced. After eight or more courses of injections 21 per cent. of the patients still have a positive Wassermann reaction. After two or more years' treatment by mercurial pills 30 per cent. give a positive Wassermann reaction. In the latter case it is naturally extremely difficult to be sure that the patient takes the remedy.

5. As regards salvarsan the danger is not great in properly selected cases. With rigid precautions taken in the preparation of the injections and with an aseptic technique the intravenous method has many advantages. The use of redistilled saline eliminates the pyrexia, rigors, vomiting, and other unpleasant symptoms in nearly every case.

6 The immediate effects of salvarsan both on the clinical manifestations of the disease and on the Wassermann reaction are far more rapid than are those of mercury. The ultimate effects in primary syphilis are remarkable; in early cases the secondary stage may be aborted. The effects in well-developed secondary syphilis are less striking and relapses certainly occur, and it remains for time to show the permanence of the results. In tertiary syphilis healing is extraordinarily rapid, but the Wassermann reaction is difficult to alter and relapses are likely to occur.

7. Everything points to the importance of early diagnosis and early treatment.

I am indebted to Dr. McIntosh and Dr. Fildes for many observations made in this paper. Their work has been most carefully carried out, and I am glad to know that it is now generally available through their valuable monograph.

Manchester-square, W.

[2] For fuller details see their monograph "Syphilis from the Modern Standpoint," published by Arnold. See also THE LANCET, vol. ii., 1910, p. 1684; vol. ii., 1911, p. 213.

INTESTINAL MYIASIS.

BY E. A. COCKAYNE, M.B. OXON., M.R.C.P. LOND.,
CASUALTY PHYSICIAN TO ST. BARTHOLOMEW'S HOSPITAL.

CASES of intestinal myiasis in this country are sufficiently interesting and uncommon to be worth recording. I met with one last summer, of which the following is a short account, necessarily incomplete because the mother of the child never came back to tell me how the case ended, nor gave me the further information which I had asked for.

Notes of case.—The child, a boy, aged 1 year and 2 months, was brought because his mother, very much alarmed, noticed that on Sept. 29th, when she lifted him up from the bed, there were a number of living "worms" under a small piece of flannel upon which he had been lying. More of these were found whenever he was left on the bed, though none were noticed elsewhere. The greatest number, probably about 50, were seen in the morning, and always under the flannel or mackintosh upon which he had been left all night. Fewer were found in the same situation during the day. They were still being found in about the same numbers when I saw the child on Oct. 2nd. The mother said that there were never any in the napkin, and that the stools were always free from them; this was certainly the case in the one which I saw, and they were found even when the child had not passed a motion. The infant, though rather poorly nourished, had

remained in his usual health and had had no sickness, constipation, diarrhœa, abdominal pain, or loss of appetite.

The "worms"—obviously dipterous larvæ, of which the mother brought about 40 in a bottle—were very active at first, but unfortunately they died before I reached home, probably poisoned by something in the bottle. I was therefore unable to breed any of the flies, but Mr. E. E. Austen, of the British Museum (Natural History), kindly examined them and identified them as larvæ of Musca domestica, Linn., the common house-fly, and one larva of Fannia canicularis, Linn., the small house-fly. He said that they were in their last instar and were probably full-grown. There is little doubt that they had left the child voluntarily, and had crawled under the piece of flannel, seeking a suitable place in which to pupate. The patient's mother said that she had not noticed many flies in the house, and that all the food was kept in a cupboard on the landing, outside the room.

Remarks.—Though Musca domestica is one of the insects which are most commonly concerned in these cases of accidental parasitism, I can only find ten recorded cases. In his paper read before the Entomological Society of London, 1837, the Rev. F. W. Hope collected three cases, in two of which the larvæ were vomited. Robineau Desvoidy in 1849 described a case with headache, vertigo, and vomiting, which ended in death. In Lublinski's case in 1885 full-fed larvæ of Musca domestica were vomited. W. M. Jones records a case which occurred in Sheffield of a man, aged 52, who passed 20 larvæ of this fly per anum; and Wirsung in 1906 gives two German cases, one in a breast-fed child aged 5 months, and the other, in which the species is more doubtful, in a child 1 year old. Mr. Austen tells me that he knows of a recent case in which larvæ of both Musca domestica and Fannia canicularis were passed together by a young baby. This is the only case I have heard of exactly like mine.

The dipterous larva most commonly found in the intestinal tract in temperate regions is that of Fannia canicularis (formerly known as Homalomyia or Anthomyia canicularis). The allied F. scalaris sometimes occurs, and Czokov records a case in which both were found. F. canicularis has also been found in company with Musca corvina and Calliphora vomitoria, the bluebottle fly. Many other species have been found in cases in temperate countries, but the condition is probably much commoner in the tropics.

One of the most curious is the rat-tailed larva of the drone-fly, Eristalis tenax, Linn., of which I find four certain and one probable case in the literature. One occurred in a child aged 1 year and 6 months, and in an Italian case it was associated with the larva of Calliphora vomitoria.

Larvæ of the following flies have been found in cases of intestinal myiasis in Europe and North America, in which the species concerned has been identified:—

Stratomyidæ.—Microchrysa (Chrysomyia) polita, Linn.
Syrphidæ.—Eristalis tenax, Linn.; Helophilus pendulus, Linn.
Œstridæ.—Tachina (Musca) larvarum, Linn.; Gastrophilus equi, Fabr., or an allied species
Sarcophagidæ.—Sarcophaga (Musca) carnaria, Linn., S. hæmatodes, Meig., S. hæmorrhoidalis, Fall.; Wohlfahrtia (Sarcophila) magnifica, Schiner.
Muscidæ.—Musca corvnia, Fabr.; M. domestica, Linn.; Lucilia (Musca) cæsar, Linn., L. regina, Macy., possibly intended for Phormia (Lucilia) regina, Meig.; Calliphora (Musca) vomitoria, Linn.
Anthomyidæ.—Fannia (Anthomyia, Homalomyia) scalaris, Fabr., F. saltatrix R.D. = scalaris, F. canicularis, Linn., F. incisurata, Zett., F. manicata, Meig.; Allognota agromyzina, Fall., is perhaps the species recorded as Musca nigra.
Micropezidæ.—Calobata (Musca) cibaria, Linn.
Piophilidæ.—Piophila casei, Linn.
Geomyzidæ.—Teichomyza fusca, Mcq.

Their presence usually causes only slight symptoms, and even in cases where thousands of larvæ are passed those most common are anorexia, nausea, colicky pain, and constipation or diarrhœa. In the more severe cases there may be vomiting (hæmatemesis has been noticed once) and diarrhœa of dysenteric character, sometimes accompanied by the passage of a little blood, and in one instance true melæna. Nervous symptoms—such as headache, vertigo, and epileptiform convulsions, which ceased with the expulsion of the larvæ—have been observed in a few cases. Chichester records one in 1806, in a boy aged 14, who had urticaria, violent abdominal pain, vomiting, hæmatemesis, and inability to speak or swallow owing to pharyngeal and œsophageal spasm; later there was loss of consciousness.

Death has occurred in four cases, but the proof that the larvæ were the direct cause is not very convincing in two of these.

There is still a little doubt as to how the larvæ gain access to the intestinal tract. It is generally supposed that ova laid on dressed meat, over-ripe fruit, sour bread, cheese, unboiled vegetables, or watercress by the various species of fly, each on the food suitable for its larva, are ingested, or in such a species as Eristalis tenax and Helophilus pendulus ova or young larvæ may be taken into the stomach in dirty water or with watercress.

It is possible, but most unlikely, in view of the strong instinct which leads almost all insects to lay their eggs on food suitable for the larva, that the fly ever lays its eggs directly on the living person, especially in such species as Eristalis tenax, the drone fly, and the black and yellow hover fly, Helophilus pendulus, or Piophilus casei, the cheese fly. The number of larvæ, several thousand, passed in some cases is far too great for one fly to lay at one time. The house-fly, for example, usually only lays its eggs in batches of about 120 to 150. But one of the strongest proofs that the ova are ingested is the comparative frequency with which the larvæ of two species of fly have been found associated, and which makes it almost certain they obtained ingress in no other way. The fact that in many instances the larvæ are only vomited also suggests that they were taken in by the mouth and developed in the stomach, as occurs normally in Gastrophilus. Chatin experimented with larvæ of Teichomyza fusca from a case of his, and he found that they not only lived for several days completely immersed in water or oil, but also survived when introduced into the stomachs of various mammals, and he proved their power of resistance to the gastric juice and small need of oxygen.

Jepson has shown that in the case of the house-fly development at 70° F. is very rapid. The ova hatch in 24 hours and the larvæ attain their full growth in 11 days, and in the hotter climate of India and Ceylon they are fully developed in 5 days. In the high temperature of the intestine it is probably as rapid as in India.

In many instances the source of infection has been traced with some certainty to tainted food, and in Hutton's case ova or larvæ of Eristalis tenax were probably swallowed in water from a golf course.

Pasquale has given the most convincing instance. He had four cases in Italian soldiers, and in the case of one of them he found that in a heap of potatoes—some of which the man had eaten, and which were beginning to decay in parts—there were larvæ identical with those passed by the soldier. The man had probably eaten them as ova, and the resulting larvæ had developed in his intestine synchronously with those in the uneaten potatoes.

The cases most difficult to explain are those in which larvæ have been passed for some months, and in two cases for some years, though in one of these there were fewer in the winter. These are almost certainly cases in which the source of infection has not been discovered, and ova have been taken into the body at frequent intervals. Even Cairns's case (which lasted for three years and in which as many as 1000 larvæ were passed in a single day) and Blankmeyer's case (which lasted 12 years) can be explained in this way, since Jepson has shown that even in this country house-flies will lay their eggs all through the winter and the larvæ will develop successfully if the conditions are favourable.

Cambridge-square, W.

DOUBLE COXA VARA WITH OTHER DEFORMITIES OCCURRING IN BROTHER AND SISTER.

BY L. E. BARRINGTON-WARD, M.B., CH.B. EDIN., F.R.C.S. EDIN.,

MEDICAL SUPERINTENDENT, HOSPITAL FOR SICK CHILDREN, GREAT ORMOND-STREET, LONDON.

THE two children who are the subjects of this communication present a peculiar collection of skeletal deformities for which it is difficult to find a satisfactory etiology. The girl, aged 9, came under observation for a well-marked double coxa vara. The parents gave a history of pains in the back and an alteration in her gait dating back 18 months only. On examining her it was found that besides the hip affection she had abnormally short arms, many joints that were enlarged or creaked on movement, and eversion of the feet. (See Fig. 1.) Systematic examination of the bones with the X rays revealed deficient, unequal, and in some cases divided development of many of the epiphyses. Inquiry of the parents elicited the fact that a younger brother, aged 6½, had lately shown signs of lameness. He was admitted to the hospital and was found to have double coxa vara of a milder degree, and also a forward luxation of the upper ends of both radii. With the X rays it was seen that ossification in most of the bones was considerably advanced for his age. Brief notes of the cases are as follows:—

CASE 1.—A female, aged 9, was admitted to the Hospital for Sick Children, Great Ormond-street, on Nov. 26th, 1910, under the care of Mr. H. A. T. Fairbank. Her parents gave the history that for the last 18 months she had complained of pains in the back after exertion and became easily tired. Pains in the joints had not been a symptom. Her previous health had been good. There was an indefinite history of a fall when a few months old. As regards family history both father and mother were healthy. A grandmother had died from consumption. There was no history of syphilis or gonorrhœa. There were seven children, one dead from whooping-cough. The eldest, a girl aged 14, suffered from heart disease and rheumatism. The others, except Case 2, were healthy and normal in every way. There had been no miscarriages.

On examination it was found that the patient's general appearance was that of a particularly bright and intelligent child of a short and stumpy conformation. All the joints of the extremities were rather prominent. (Fig. 1.) The upper and lower limbs looked short in comparison with the trunk. The trochanters were very prominent, and there was some lordosis. Both femora showed well-marked coxa vara. The trochanters stood out prominently and were displaced upwards, on the right side to half an inch below, and on the left side to the level of the anterior superior spine. The subpubic angle was much increased. At the right hip-joint flexion and slight extension were possible, and to a very slight degree abduction and external rotation. No other movements were allowed. The left lower limb was held slightly abducted. No movements took place at the left hip except flexion and a little extension. Creaking could be felt in both joints. The knee-joints were in keeping with the other joints in being somewhat prominent. The enlargement was abrupt and irregular, rather than fusiform. The movements were free, and except creaking there was nothing further to note. Both feet were everted, but the arch was good and there was no flat-foot.

In the upper extremity the shortness of the limbs was obvious, in the vertical position the finger tips only reaching to 3½ inches below the tips of the trochanters. In a healthy boy of nearly the same age and size the fingers reached to 6½ inches below the upper limit of the trochanters. The shoulders were normal, except for the adventitious sounds on movement. The elbows were symmetrically enlarged. At the elbow flexion and extension could be performed perfectly, but pronation and supination were incomplete. There was considerable thickening of the internal condyle and the head of the radius could be luxated slightly forwards by pressing from behind. Crackling could be felt on movement. The wrists were rather larger than normal, but there was no alteration in bony points or movements. The fingers were short and flat, with prominent interphalangeal joints. Flexion was freely performed at the interphalangeal joints, but could not take place at the metacarpo-phalangeal. In other words, as the patient herself vouchsafed, she "could not make a fist." This is interesting, inasmuch as her brother (Case 2) presented a similar deformity. The parents stated that this condition had been present since birth. The X rays did not give any clue to the cause of this disability. The movements of all the joints were entirely painless. The circulatory and respiratory systems were normal. The teeth were good; there was no digestive disturbance. There were a few small glands palpable on the right side of the neck, but the rest of the body was free, and the spleen was not enlarged.

CASE 2.—A male, aged 6½, came under observation on Dec. 24th, 1910. In the course of questions concerning the family history of Case 1 it was ascertained that another child had developed lately a peculiar gait. He was accordingly brought to the Hospital for Sick Children and admitted under the care of Mr. Fairbank. It was then found that he was the subject of coxa vara also. The history given was that the change was noticed first ten months previously. No cause could be assigned. The patient had been otherwise perfectly healthy in every respect. He looked a healthy and intelligent boy, without any signs of deformity excepting enlargement of the elbow-joints, a tendency to lean forwards when standing due to slight flexion at the hips, and an almost waddling gait. The left lower limb had half an inch of shortening; the trochanter was displaced above Nélaton's line to half an inch below the level of the anterior superior spine; abduction was slightly, rotation inwards greatly, limited. On the right side the trochanter was displaced upwards to 1 inch below the level of the anterior superior spine. Both the trochanters were prominent, and both hips slightly flexed, but there was no true lordosis.

In the upper extremities interest centred chiefly on the elbows. It was found that there was a forward luxation of the upper ends of both radii. (Fig. 5.) The upper end of the radius formed a visible projection in front of the external condyle and could be grasped easily between the finger and thumb, and the finger could be inserted into the concave upper surface of the radial head. All movements were performed well, and the boy had perfectly useful joints. The condition was quite symmetrical on both sides. The interphalangeal joints of the fingers were prominent, especially in the case of the middle finger of the left hand. As in Case 1, flexion could be performed at the interphalangeal joints, but not at the metacarpo-phalangeal. The spine, ribs, and clavicles were normal. The teeth were good and the cardiac and respiratory systems were sound. There were no enlarged glands, and the spleen was not enlarged.

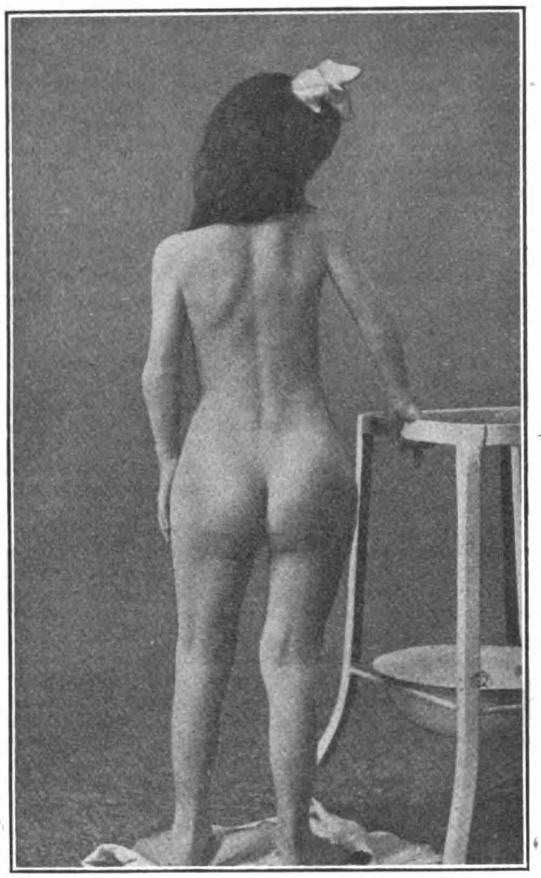
It is on examining the skiagrams that the peculiarities of the cases are manifest. Unless stated to the contrary, it may be taken that the abnormalities are the same on both sides, differing only in degree.

In the hip-joint of Case 1 the epiphysis is quite undeveloped and appears as a thin scale-like shadow in the acetabulum. The neck, on the other hand, is greatly thickened, giving the impression of considerable bony proliferation. The edge of the acetabulum is woolly and indistinct. The shaft of the femur is abnormally thin.

In the lateral view of the knee-joint the curious condition of the patella is seen. (Fig. 2). It appears to be ossifying in four separate and unequal portions. In the antero-posterior view the outline of the patella can be distinguished over the external condyle. On the inner side is an apparent loose body with a corresponding depression in the inner condyle. It is difficult to explain this except perhaps as a separately ossifying part of the femoral epiphysis. Were the patella not to be seen on the outer side, it might be taken as one of the parts of that bone seen in the preceding skiagram.

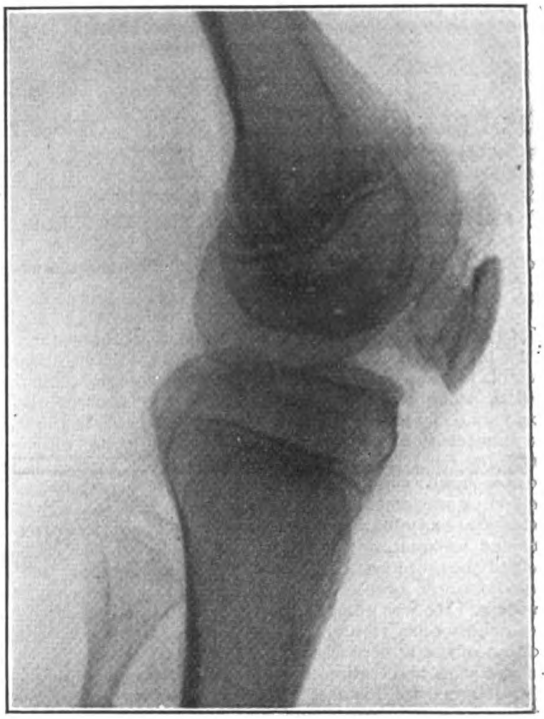
The skiagram of the tarsus shows the advanced ossification of the bones. (Fig. 3.) But, in addition, there is seen a new

FIG. 1.



Reproduction of photograph of Case 1, showing the prominence of the joints, the shortness of the arms, and the deformity of the hips.

FIG. 2.



Skiagram of left knee-joint, Case 1, showing the patella ossifying from four centres.

FIG. 3.

Skiagram of right foot, Case 1. The extra-tarsal bone is well seen between the scaphoid and internal cuneiform bones. The ossification is advanced for the age.

element in the shape of a wedge-shaped piece of bone intervening between the scaphoid and the internal cuneiform. This may be regarded from its outline as a separate part of the cuneiform. It is only present on the right side.

Ossification appears advanced in the skiagram of the wrist and hand. At the lower end of the radius is seen a rarefied area sharply marked off from the rest of the shaft. The

FIG. 4.

Skiagram of right hip-joint, Case 2, showing (1) flattened undeveloped epiphysis of the head of the femur, and (2) expansion and overgrowth of the neck.

semilunar bone of the wrist appears to be displaced upwards, for its shadow distinctly overlaps that of the radius. The lower epiphysis of the ulna is unduly small.

The skiagrams of the hips of Case 2 show the undeveloped scale-like epiphysis of the head set on a greatly expanded neck. (Fig. 4.) The epiphysis is displaced upwards and the neck appears to have proliferated beneath it to meet the acetabulum. In the skiagram of the knee the patella does not appear as a shadow at all. Both femoral and tibial epiphyses have an indistinct outline. On the other hand, the bones of the feet are as much ossified as those of a child some years older. The skigrams of the elbow-joints show clearly the forward luxation of the upper ends of both radii and the delayed ossification of the radial epiphysis. (Fig. 5.)

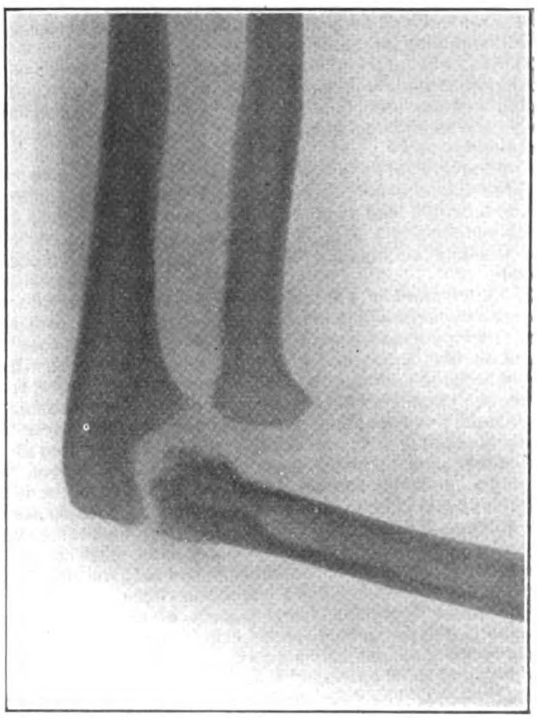
To sum up, the most interesting point in these cases is the general advance of ossification in the diaphyses, and the unequal, deficient, and, in some instances, divided development of the epiphyses of many of the bones. At first sight the clinical appearance was not unlike the osteo-arthritis occasionally met with in children. The stiffness and enlargement of some of the joints, the creaking, the coxa vara, the deficient movement at the elbows, and the fingers rather suggested it. The enlargement of the joints was slight; they are described best as prominent; they did not approach the fusiform shape that characterises rheumatoid arthritis. Moreover, the increase in size was due to slight enlargement of the ends of the bones, not to peri-articular thickening. Rickets did not seem a reasonable explanation. The X ray appearances are quite unlike rickets. Still's disease, also, could be excluded. Except for their deformities the children always have been and are in perfect health. No general enlargement of glands or of the spleen could be detected.

The shortness of the arms in Case 1 and the mental characteristics of both suggested achondroplasia, but the history alone, apart from the absence of the other distinguishing features, negatived that. The phalanges were not sufficiently enlarged to merit the term of "clubbed digits," but some of the changes shown by the X rays rather resemble those of osteo-arthropathy—Marie's sign group. Bamberger has described thickening of the ends of the shafts of long bones and also rarefaction with erosion of the articular cartilages. This is not unlike what has occurred in the lower end of the radius in Case 1. The absence, however, of the typical clubbed digits enables us to exclude that affection. It was not until systematic examination of the osseous system was made with the X rays that a fuller knowledge of their peculiarities was revealed. It was then seen that a large number of the epiphyses were abnormal. In the knee-joint the patella is ossifying in several parts; a small portion of the lower epiphysis of the femur is separate. In the tarsus there is an extratarsal bone, probably a part of the internal cuneiform developing from a separate centre. It is not very uncommon for this bone to develop in two parts.

The double luxation of the radius in Case 2 is undoubtedly of a congenital nature, and we are justified in assuming, I think, that this is not a separate condition, but that it has a bearing on the case as a whole. In a case recently reported Belot and Chaperon attributed the double luxation to the dystrophic action of hereditary syphilis. There is nothing either in the history or the physical appearance of these children to support that theory.

Maldevelopment of the epiphyseal ends of bone is always a factor to be considered in the causation of congenital dislocation of joints. It has been given as a cause in congenital dislocation of the hip by Bowlby and Lockwood, and some cases of congenital dislocation of the shoulder are due to deformity or absence of the glenoid.

FIG. 5.



Skiagram of right elbow-joint, Case 2, lateral view. The dislocation of the head of the radius is well shown.

That the epiphyseal development is, in part at least, abnormal in these cases is, I think, clear. What the real etiology of this abnormality is remains doubtful.

I am much indebted to Mr. Fairbank for permission to publish these cases, and also to Dr. W. Ironside Bruce for taking the skiagrams and assisting in their interpretation.

Great Ormond-street, W.C.

THE FUNCTIONS OF THE TONSILS AND THE APPENDIX.

BY KENELM H. DIGBY, F.R.C.S. ENG., M.B., B.S. LOND.,
LATE SURGICAL REGISTRAR, GUY'S HOSPITAL.

IN the investigation of acquired immunity far more attention and investigation have been given to the modes of action of various antibodies in the blood stream than to the tissues in which they have been produced. But there are fairly good reasons for supposing that the spleen, the bone-marrow, and the lymphatic glands are the chief antibacterial workshops.

In this note it is proposed to deal only with a group of lymphatic structures whose antibacterial activity is not commonly considered, and, indeed, is hardly recognised. These lie close to the surface of the body, and can be called the subepithelial lymphatic glands. In this group are included the tonsils—nasopharyngeal, faucial, and lingual, the solitary follicles of the intestine, Peyer's patches, and the vermiform appendix.

The hypothesis to be advanced here is that these particular lymphatic structures protect the body against chance infection by a process of continual auto-vaccinations. Any bacteria in the vicinity are attracted by positive chemiotaxis through the overlying epithelium into the lymphatic nodule. The bacterial attack, having been invited in a region most favourable to the defensive mechanisms of the body, is nearly always repulsed. In accordance with that over-production which is so characteristic of biological response, specially trained lymphocytes and a great excess of specific bacteriolysins and antitoxins are produced. These enter the general system and lessen the risk of a successful bacterial infection at a more vulnerable part. Thus, more or less immunity against organisms is acquired by the individual without his obviously suffering from disease. On rare occasions the lymph nodule is overcome and the disease develops; but the body has meanwhile become better able to withstand a general invasion.

The facts in favour of this hypothesis are as follows:—

Anatomical.—1. *Position* of the subepithelial glands. The lymph nodules are placed directly beneath the epithelium. They are superficial even to the fibres of the muscularis mucosæ.

2. *Structure* of the subepithelial glands. Where the follicles are crowded together the overlying epithelium is folded into pits and recesses so that each lymph nodule subtends the surface. This is well seen in the nasopharyngeal and the faucial tonsils. There are no afferent lymphatic vessels.

3. *Distribution* of the subepithelial glands. They do not underlie the skin which is thick, resistant, and comparatively free from pyogenic organisms on the surface, but they are found in the throat and along the alimentary tract, where the mucous membrane is thin, permitting of absorption. Moreover, they occur exactly at those points where the micro-organisms flourish. The circumpharyngeal ring meets the bacteria entering with the food (and with the inspired air in the cases of mouth-breathers). The Peyer's patches, the appendix, and the solitary follicles are placed around the excellent incubating media in the ileum, cæcum, and ascending colon, precisely those parts which are swarming with organisms. The stomach, on the other hand, protected from bacterial growth in its contents by the acid nature of its secretion, is almost free from lymphatic tissue.

The whole anatomical arrangement of the subepithelial lymphatic glands is such as to bring them into close connexion with the chief collections of bacteria lying outside of, but adjacent to, the tissues.[1]

Clinical.—1. The subepithelial glands bear the *brunt of the attack* in faucial and intestinal infections. Scarlet fever, typhoid fever, and appendicitis are sound examples. In infantile enteritis the Peyer's patches are swollen and infected.

2. The subepithelial glands are largest and most active in young children at a period when individuals are acquiring immunity to the various common infections. In old age all lymphatic structures tend to atrophy.

3. The subepithelial glands hypertrophy as a result of repeated infectious diseases. Whooping-cough, scarlet fever, measles, and "colds" (especially if associated with deficient exercise or unhygienic surroundings) lead to enlargement of tonsils and adenoids. General increase of lymphatic structures signifies prolonged bacterial assaults, and may be accompanied by a toxin-weakened heart—the so-called status lymphaticus.

4. It is often observed during scarlatinal epidemics that a person may apparently secure immunity by a very mild tonsillitis which is unaccompanied by rash, malaise, or other signs of general injury.

5. In fulminating infections, where septicæmia is early and fatal, the lymphatic reaction is poorly developed.

Thus clinical evidence provides abundant proof of the important part played by subepithelial lymphatic glands in bacterial infections. The glands are the tissues first affected and most involved. As a rule, the tissue which is most seriously attacked provides the greatest number of antibodies. For instance, the power of brain emulsions to neutralise tetanus toxin has been satisfactorily proved.[2] Finally, there is evidence that immunity can be acquired without the general development of the disease.

Pathological.—1. Paraffin sections of the faucial tonsils repeatedly show bacteria passing through the covering of stratified epithelium and entering the lymph nodes.

2. A larger number of mitoses are seen in the lymph nodes of subepithelial glands in certain infections.

3. The lymphocytes are formed in lymphatic glands. In faucial and intestinal infections these cells are increased in number in the blood. A lymphocytosis accompanies polynuclear leucocytosis in pyogenic inflammations, and occurs alone, or predominantly, in scarlet fever, measles, variola, infantile gastro-enteritis, some cases of diphtheria, pertussis, rickets, and syphilis. In enteric fever, although there is a diminution of the total number of white corpuscles, yet the lymphocytes are increased in number. The almost constant presence of lymphocytes about an infected area seems to indicate that these cells play an antibacterial part. In connexion with the greater activity of the lymphatic tissues in children, it is interesting to note that a lymphocytosis is more easily provoked in early life.

Biological.—1. In the fierce struggle for existence types possessing useless organs are little likely to perpetuate their kind. And when the organs are, like the tonsils and the appendix, so often the seat of deadly diseases, their eradication from the race would soon be brought about had they not a more than counterbalancing protective action for their owner. The argument is, admittedly, incomplete; but at least it is fair to say that, from a biological point of view, the probability is that both the appendix and the tonsils are of more value than current opinion allows.

2. The comparative anatomy of the subepithelial lymphatic glands has received very little study. If it should be found, as seems likely, that the lymphoid tissue is better developed in those animals, such as the herbivora, where the food takes longer to digest and so allows of extra bacterial growth, it would be another point in favour of the hypothesis.

If this hypothesis is accepted as a working one, it is natural to inquire how it should affect the treatment of disease.

In the first place, the surgeon will be more than ever disinclined to sacrifice the appendix or the tonsils and adenoids unless he is quite convinced that they are dangerous or injurious. When, however, appendicitis has definitely occurred once, it is so likely to recur, and the recurrence to prove dangerous, that the appendix should be removed even if the exterior appears healthy. Besides, there is still some lymphoid tissue left in the cæcum which may be equal to the increased demands upon it. But one wonders whether a few of the cases of coli bacilluria and cystitis are not due to previous disease or removal of the appendix.

Similarly, the obvious benefit of removing adenoids, which are completely obstructing nasal respiration, is so considerable that no surgeon should stay his hand for a theoretic disadvantage. But the removal of a slight enlargement of the naso-pharyngeal tonsil consequent upon an otorrhœa may deprive the patient of the means of vaccinating himself against the organisms in the pus escaping from the Eustachian tube.

[1] The Subepithelial Lymphatic Glands, Guy's Hospital Gazette, May 13th, 1911.

[2] Ehrlich: Studies on Immunity, Section XXXI., New York and London, 1906.

In the second place, the hypothesis may lead to fresh methods in preventive medicine. If during a scarlatinal epidemic a slight infection of the tonsils without a true attack will immunise the individual the physician may take charge of the process and apply infective material (in which the unidentified organisms have been destroyed by heating) to the tonsils of those not previously attacked. The dead organisms would be drawn into the lymphoid tissue and antibodies formed. Or feeding with dead typhoid bacilli might protect against typhoid fever. But these methods would have this danger, that the consequent reaction in the subepithelial glands, if too severe, might pave the way for a secondary infection.

The hypothesis would seem to have this merit, that its tenets and conclusions can be further investigated without great difficulty.

ROYAL SOCIETY OF MEDICINE.

SURGICAL SECTION.

The Talma-Morison Operation.

A MEETING of this section was held on Jan. 9th, Mr. CLINTON T. DENT, the President, being in the chair.

Mr. RUTHERFORD MORISON read a paper on the Operative Cure of Ascites due to Liver Cirrhosis. He said that during a visit to the post-mortem room Dr. David Drummond showed him the body of a man dead from cirrhosis of the liver and explained that this patient had no ascites because the collateral circulation, chiefly through the enlarged veins of Sappey, had relieved the portal obstruction. He (Mr. Morison) suggested that if his explanation was correct, it might be possible to cure an existing ascites by an operation, which would establish a new anastomotic circulation. In regard to the ordinary connexions between the portal and systemic circulations, when adhesions form between the viscera and parietes, innumerable new vessels develop in them and convey blood freely from the portal into the systemic circulation through the subperitoneal plexus of veins. Probably the most important of these new channels could be developed in adhesions between the omentum and parietes. A study of Nature's methods suggested that operation might be useful in selected cases, for they were familiar with the enormous newly-formed blood-vessels frequently met with in the portion of omentum adherent to rapidly growing abdominal tumours; they had seen adhesions of all sorts in the abdomen develop large vascular channels, and they knew that such vascular adhesions could form with considerable rapidity. Other factors besides mechanical obstruction of the portal vein doubtless aided the development or retarded the arrest of ascites due to cirrhosis; but his cases proved at least that the establishment of an artificial circulation could cure it. Experience had confirmed that view, but, as he had always been careful to point out, the cases in which operation could be of use were rare and must be carefully selected. So far as he knew, the most suitable were those of alcoholic cirrhosis in patients otherwise sound, and whom repeated tapping had failed to cure. None of those cases had in their experience been failures. The reason probably was similar to that of the cure of dropsy from heart failure following persistent over-strain. In both the chief predisposing cause of the dropsy could be removed, in the case of the heart by rest, in the case of the liver by abstinence from alcohol. That explanation seemed probable because though he had operated upon patients in good condition with ascites due to syphilitic cirrhosis, none of them had been cured. The most unfavourable cases were those which at their commencement simulated an abdominal emergency and sufferred from pain and tense tympanites preceding the development of ascites. In operating, the choice of an anæsthetic might be of importance. The great danger in these cases appeared to be the development of a condition related to acute yellow atrophy, and chloroform, as was well known, could produce similar hanges in the liver, so that some other anæsthetic should be chosen. The abdominal incision should be made above the umbilicus to avoid the development of a ventral hernia. The steps of the operation were: (1) Open the abdomen from the ensiform cartilage to the umbilicus; (2) introduce the hand into the abdomen and project a finger against the anterior parietes in the middle line three inches above the pubis; (3) make a small incision on to the finger-tip, and through that introduce a long small glass drainage-tube into the recto-vesical or recto-uterine pouch; (4) dry the abdominal cavity and scrub the peritoneum with mops; (5) suture the omentum to the anterior parietal peritoneum across the abdominal wall and close the upper abdominal wound; (6) apply an antiseptic dressing over the wound and tube, and over this, from above down to the tube, a series of long circular strips of adhesive strapping, with the object of keeping the parietal in contact with the visceral peritoneum; (7) the tube now exposed through the dressings is surrounded with a sheet of dental rubber perforated to grasp it below the collar on it, and the separated tube dressing is wrapped up in the indiarubber sheet. For after-treatment a nurse was engaged to attend to the tube and pump off the fluid sufficiently frequently to keep the dressings dry. If that could be accomplished the dressings required no change for ten days, after which, as a rule, a small indiarubber tube could be made to take the place of the glass one. He had heard of septic peritonitis resulting from that operation. In Newcastle they had never seen that, and it might be that their free use of antiseptics during the operation and in the dressings was the explanation. As a rule the wounds were entirely healed in one month, and no further accumulation of fluid occurred. It need, however, occasion no serious disappointment if the fluid re-accumulated, as some of their most successful cases had required tapping on one or two occasions after recovery from the operation.

Dr. W. HALE WHITE said he agreed with Mr. Morison that the cases of cirrhosis for which this operation was suitable were rare; he would say they were extremely rare, and that other factors than pressure on the portal vein were usually operative in the production of ascites. He pointed out that none of the cases in which Mr. Morison claimed success were ordinary examples of cirrhosis. The operation would be even less used in the future, for the consumption of alcohol was decreasing, and only a quarter of those who had cirrhosis had ascites. That pressure on the portal vein was the chief factor in causing ascites was unlikely, for the effusion of fluid might be sudden; the liver might be very contracted without ascites; there might be ascites and yet the branches of the portal vein might be normal, and ligature of the portal vein usually did not cause ascites, or if a little fluid was poured out it was quickly re-absorbed. The ascites was probably toxic, and cirrhosis of the liver should be regarded as a local disease of the liver causing many general toxic symptoms. The poison produced by the liver was lymphagogue; hence swelling of the feet, certainly not due to pressure on the vena cava, pleural effusion, ascites, a raised temperature, and coma—all often seen in cirrhosis. The appearance of ascites was a serious symptom, for in uncomplicated cases it indicated that the end was not far off, nearly every patient being dead within two months of the appearance of the ascites; hence in uncomplicated cases operation was useless. As a rule, when a patient with cirrhosis survived many tappings, some contributory cause to the ascites was present. Further, it must be remembered that dogs in which a communication between the portal and general venous system had been made died.

Dr. H. D. ROLLESTON said that the rationale of the Talma-Morison operation was not, he believed, merely opening up a collateral circulation; if that was carried to excess the condition resembled that of Eck's fistula in which uræmic symptoms were apt to supervene. Patients after the Talma-Morison operation indeed might for some time exhibit some symptoms of mental disturbance. The increased anastomosis probably acted by diminishing the blood flow to the liver, and enabled the liver to deal more satisfactorily with the blood passing through it and so reduce the toxæmia which was probably the main cause of ascites. The changed blood-supply to the liver might so improve the nutrition of the liver cells as to allow compensatory hyperplasia of the liver cells. The operations consisting in permanent drainage into the subcutaneous tissues (Schiassi, Narath, Handley) or into the saphena vein (Routte, Celso) were on a different footing from

the Talma-Morison operation, as they did good by removing the fluid and could not be thought to improve the nutrition of the liver. Possibly those operations might act in the same way as autotherapy—i.e., injection of ascitic fluid into the subcutaneous tissues of a patient with cirrhotic ascites—did. The Talma-Morison operation was of value in selected cases—namely, cases in which ascites occurred in patients who were in such good condition that they could stand the operation, and in whom there was a sufficient amount of liver substance left to undergo compensatory hyperplasia and carry on the antitoxic functions of the liver. The contra-indications to the operation were: (1) an advanced stage of the disease as shown by debility, wasting, and considerable toxæmia; (2) considerable jaundice; and (3) definite kidney or heart disease. These cases were rare; they were presented by cases in which ascites appeared soon after hæmatemesis. His own experience was confined to three cases; one survived two and a half years, another about six months, and a third died soon after operation. He did not agree with Dr. Hale White's view that ascites in cirrhosis seldom or never required tapping more than once; he did not think that was quite correct.

Mr. H. J. WARING said that during the past 10 years he had frequently practised the operation of omentopexy. In his first cases he fixed the omentum to the parietal peritoneum, and in a few cases scarified the surface of the liver before fixing it to the deep aspect of the abdominal wall. In his later cases he had, after making a median incision, incised the umbilicus and then freely opened the rectus sheath on each side; a large portion of the great omentum was then spread out within the sheaths of the rectus on each side and anchored by a few sutures, taking care to avoid the inclusion of any of the large omental veins. In his opinion this procedure brought into contact a large area of the omentum with the superior and deep epigastric veins of the abdominal wall. The results obtained from this latter operation were far superior to those obtained by the former operation. He stated that the cases most suitable for the operation of omentopexy were comparatively early cases of ascites due to cirrhosis of the liver in patients who were not old and in whom there was no evidence of digestive disturbances consequent upon toxic absorption. Emaciated people the subjects of cirrhosis of the liver, especially those with jaundice, were entirely unsuitable for the operation.

Mr. W. SAMPSON HANDLEY, after referring to the reader of the paper as the pioneer in the successful treatment of ascites by operation, said he was inclined to think the drainage methods more recently developed at the Middlesex Hospital were preferable to epiplopexy. He admitted, however, that the materials for forming a judgment as to the best operative method in ascites were not yet to hand. He thought the cause of knowledge would be best served by a parallel development of the various methods in the hands of different surgeons. But in any case the surgical treatment of ascites, though applicable only in selected cases, had come to stay. The surgical methods used in ascites belonged to two categories. Either they aimed at diverting the blood current from the congested portal system to the systemic vessels or at facilitating the resorption of the ascitic fluid. The first method, that of Mr. Rutherford Morison, though at first sight more rational, could only reinforce a collateral circulation, which was anatomically known to be a free one. If it produced any large increase in the area of the collateral channels it brought with it the danger of intoxication by unfiltered intestinal products. He did not deny its success in certain cases, but he believed its effects were largely dependent upon the peritoneal drainage which accompanied it and upon the leakage of ascitic fluid into the subcutaneous tissues at the point of implantation of the omentum. If that was so the same effects could be secured more simply and safely by the drainage methods. He considered femoral drainage (Wynter's operation) as the operation of choice. When it failed drainage by silk threads (lymphangioplasty) should be used unless the ascitic fluid was being secreted at a very rapid rate. This had been the apparent cause of failure in two of his cases. The first case in which lymphangioplasty[1] was done had now remained well and able to work for two years, although she had not given up her alcoholic habits. Recently Mr. R. Atkinson Stoney had recorded a successful case. A third method consisted in implanting the saphenous vein into the peritoneal cavity. His experience of this operation consisted of one unrecorded failure in April, 1910. At the time he did not know that the operation had been tried. The valves of the vein proved to be incompetent, and bleeding occurred from its proximal end. The fourth method, recently recorded by a Dublin surgeon, consisted in implanting the external saphenous vein into one of the portal tributaries. The recorded case was a failure, but the method had future possibilities, though it brought with it the danger of toxæmia. In regard to autoserotherapy he wished physicians would try it for a while as a routine measure after tapping ascites.

Dr. W. ESSEX WYNTER said that the actual cause of ascites was too long and complicated a matter to go into at the moment; the practical point was that, on the one hand, the peritoneal cavity was over-distended with a benign nutrient fluid which hampered the circulation and respiration by its bulk, and on the other, the system was starved of nutrient and fluid, the want of which resulted in wasting and toxæmia. Though it had scarcely been mentioned, one of the most striking features of ascites was the tendency to anuria accentuated at each paracentesis. The problem that presented itself was the transference of the ascitic fluid to the general circulation, and for the patient the avoidance of the detention and loss of activity inseparable from the old method of repeated tapping. He had secured this in some cases by getting a surgeon to open up the femoral ring and so drain from the lowest available point of the abdomen into the upper region of the thigh. The greatest difficulty resulted from the tendency of the peritoneum to close any breach in its continuity. In one recent instance where the patient was kept lying up for three weeks by a leakage at the femoral incision a pouch formed as large as the two fists limiting the extension of the serum to this region by the development of an endothelial lining. It was not, however, essential to maintain perpetual drainage, it being sufficient to establish it for a few weeks so that by relief of tension in the abdominal walls the normal collateral circulation could expand. In the Talma-Morison operation this was effected by the continuous drainage into the dressings after the evacuation of the cavity, for it could hardly be contended that the small addition to the collateral circulation afforded by the epiplopexy can be of any serious importance. One of the principal channels concerned in the re-establishment of the circulation was the vena azygos major, whose radicles below the diaphragm were often as large as the forefinger in such cases. It was a matter of disappointment in the majority of instances that the drinking habit continued; both those recently shown at the Clinical Society after three and four years' freedom from ascites were still steady tipplers, and another case had returned to hospital only a fortnight after her discharge the worse for liquor. The more promising would certainly be the scarce non-alcoholic cases of cirrhosis and those of chronic peritonitis.

Mr. SINCLAIR WHITE (Sheffield) wrote stating that he had operated on 19 patients and had had five deaths directly due to the operation; three from anuria with mild delirium passing on through coma to death at about the end of a week; one from septic peritonitis on the eleventh day, consequent on bursting open of the abdominal wound during a fit of coughing; and one from exhaustion on the fourth day, in which there was free venous oozing from the omentum. Of the cases which recovered from the operation, four were not appreciably benefited. In three cases the ascites did not completely disappear, but some improvement in health occurred; all three, however, died within 12 months from the date of operation. In the remaining seven cases the ascites gradually disappeared, in two of them not until subsequent tapping had been done, and a more or less complete return to good health ensued. Unfortunately, in two instances a relapse to intemperate habits, in one patient after an interval of nearly two years, ruined what promised to be permanent recoveries. One patient is in robust health after aninterval of nine years; a second was, a few months ago, reported to be quite well after an interval of nearly six years. A third died from carcinoma of the colon two years after operation without recurrence of the ascites. The two remaining cases had been operated on during the last 12 months, and both promised well. Operative measures should be restricted to: (*a*) securing adhesions between the anterior surface of the great omentum and the posterior

[1] Handley: Hunterian Lectures on the Surgery of the Lymphatic System, THE LANCET, April 9th (p. 977) and 16th (p. 1052), 1910.

surface of the right rectus muscle. He made a 6-inch vertical incision 2 inches to the right of the linea alba, reflected the peritoneum and posterior layer of the rectus sheath outwards and inwards, implanted the omentum into the pocket thus formed, and secured it by a few interrupted sutures, taking great care not to puncture the omental vessels. (*b*) Peritoneal drainage through a suprapubic opening for from six to ten days. A progressive increase in the amount of urine excreted from the third day onwards nearly always took place in patients who did well. From a surgical point of view cases of cirrhotic ascites might be conveniently divided into two classes. In one of these, owing to a well-developed anastomosis between the portal and systemic veins, ascites appeared only as a terminal symptom, and not until the liver cells were hopelessly damaged and there was present accompanying degeneration of the vascular and possibly renal systems. Patients of that class were rarely difficult to diagnose. The congested skin with spider-webbed angiomata of the face, often an icteric hue in the conjunctivæ, great loss of strength, rapid wasting of the upper half of the body, acute progress of the ascites with œdema of the legs and genitals, and pronounced dyspnœa and tachycardia on slight exertion were the sure harbingers of death which no operation could avert. In the other class the collateral circulation was imperfectly developed, and ascites of gradual onset appeared as a comparatively early symptom before the hepatic cells had undergone serious degeneration. In many of those it would appear that the incidence of the poison (alcohol or other) extended to, and was most marked on, the peritoneal covering of the liver, hence an extensive and pronounced perihepatitis was commonly found associated with a greater or lesser amount of interstitial fibrosis. The patients were usually under the age of 50 years, might have quite healthy vascular and renal organs, and, apart from the abdominal distension, might be in fairly good health. Those were the cases which derived great benefit from epiplopexy, and, generally speaking, it should be restricted to them. There were, of course, borderland cases where the expediency of operating would give rise to anxious consideration. When in doubt one or more tappings would often help them to arrive at a decision. Indeed, in all cases a preliminary paracentesis was of value.

Mr. W. G. SPENCER said that if he differed from Dr. Hale White it would be because he had had no experience of the acute form of ascites rapidly running on to death. Dr. Hale White had drawn a distinction between ascites and ascites due to alcoholic cirrhosis. His remarks might apply with limitations. But there was the practical point against the latter part of Dr. White's statement and that was the great advantage of an exploration of the abdomen for the cases of ascites which had been repeatedly tapped. Following upon the appearance of Mr. Morison's first paper, physicians—Dr. de Havilland Hall, Dr. Murrell, Sir William Allchin, and others—had sent him cases, in some of which the great value of the operation had turned upon the exploration of the abdomen. Others had been definitely cases which came under the heading of those described by Mr. Morison. Mr. Spencer mentioned several cases in which exploration had been important. One, under Dr. de Havilland Hall, was tapped ten times and after each tapping carefully examined, but nothing was found until the abdomen was explored, and then it was discovered that she had two small papilliferous ovaries, which were removed, and the patient was shown some time afterwards, the condition having been cured, at the Medical Society. She was a housewife, looking after a family of ten children, and she continued well. The second was in a young man who was tapped, and no explanation could be given until the abdomen was explored, and then a contracted adherent appendix was found. When that was removed the lad got well and remained so. Mr. Lockwood said that that was an exceptional case; no doubt it was, but it was worth mentioning. A third patient was tapped several times and later drained. It turned out on exploration that the cause of her ascites was pelvic peritonitis traceable to a puerperal condition, and she was cured by fixing the omentum after Mr. Morison's fashion. He showed her at the Medical Society some time afterwards, and she had remained well, the date of exhibition being 1903. There was another case, an obscure abdominal condition, under the care of Sir William Allchin. The patient was invalided as a hopeless case. On exploration it turned out that his ascites must have been due to chronic inflammation of the duodenum with peritoneal inflammation around. He was cured after the omentum had been fixed to the abdominal wall. He developed veins, though they were not so marked as in the photograph Mr. Morison showed. He was taken back by his firm after an illness of eight years. Mr. Spencer had fixed the omentum in atrophic cirrhosis of the liver, and the cases had been relieved from further tappings, but they had remained in bed without general improvement, and had died. One woman had a liver half the normal size and lived only five weeks. He had not lost one of those cases from the operation. Of the hypertrophic cirrhosis of liver cases he would not say they were cured, but they remained a long time without return of the fluid. Perhaps they did not all accord with Dr. Hale White's connexion of ascites with cirrhosis, but there was one alcoholic patient who had been tapped many times. She was a typical besotted old woman who said she drank as much as she could get, and probably she did. She was shown at the Clinical Society four years after fixation of the omentum without any reaccumulation of fluid. She afterwards developed most rapid carcinoma of the breast, which was removed. It recurred six months afterwards, and she died. At the post-mortem examination an anastomosis was seen such as Mr. Morison described, but there was no fluid. Her statement regarding the four years was that she continued to drink as much as she could get, though perhaps that was not very much. One case, under the care of Dr. Hall, was well for five years, then he returned and was tapped; this was followed by heart changes and he died. Another case was one which Dr. Murrell called a variety of Banti's disease. It was that of a girl aged 25, who had inflammation of the lungs, followed by ascites and repeated tappings, and she had enlargement of the liver and spleen. After the operation she was relieved for one and a half years, and went back to her work. Then she relapsed and after further tappings died. The patient showed anastomosis. He could mention two other cases which were moderately unfavourable. In both the patients wished for something done instead of being continually tapped. A case under Dr. Hall and Dr. Roger Smith, of ascites with hypertrophy of the liver and cirrhosis, was that of a patient who had been seen by two consulting physicians, one of whom gave her three months to live and the other six months. The patient was weary of the tappings and she urgently wished operation. The first operation, done in 1909, was by Mr. Morison's method. That relieved her for nine months. When the ascites recurred and tapping became again necessary she wished a second operation. So he adopted Dr. Wynter's method of putting tubes, one in each femoral canal, and they conducted the fluid into her legs, which had to be kept raised. Later those tubes became blocked with fibrin and the fluid re-collected in the abdomen. She then decided upon a third operation, and as there was a moveable kidney it occurred to him to decapsulate the moveable kidney and dissect off a neighbouring piece of peritoneum. That operation again relieved her from the need for continual tapping. Later, at a fourth operation, he adopted Mr. Sampson Handley's method, taking double strands of long silk, putting them from the pelvis through the abdominal wall up to the breast, axilla, and kidney. That had not cured the patient, but tapping was required less often. The other day she was tapped for the thirty-fifth time, and her liver then reached down to the umbilicus. He did not know the cause of the ascites. In another woman he varied the operations. She had been improved for a time by the Drummond-Morison method, and thought so much of it that she wanted something more done. At the second procedure he did what was first proposed by Mr. Turner, of St. George's Hospital—namely, scraping the liver very hard. That relieved the patient for a time. Dr. Peter Paterson, of Glasgow, had invented a method of putting glass buttons in the abdominal wall, and Mr. Spencer, at a third operation, relieved this patient for a time by inserting a button. A case under Dr. W. G. Stone had ascites complicated by diabetes. He died five weeks after epiplopexy in diabetic coma. Both the diabetes and ascites were due to the formation of pancreatic calculi. Dr. Stone injected the omental vessels and found that a good anastomosis with the abdominal wall had already occurred. Mr. Spencer had never seen any harm come from these operations, and he was sure the patients' lives were prolonged. It

was a procedure which surgeons should urge, for it incidentally brought about an exploration of the abdomen.

Mr. G. H. MAKINS and Dr. F. PARKES WEBER also joined in the discussion, which was concluded by a brief reply from Mr. MORISON.

CLINICAL SECTION.

Exhibition of Cases.—Relative Value of Immediate and Delayed Laparotomy in Pneumococcal Peritonitis.

A MEETING of this section was held on Jan. 12th, Sir WILLIAM OSLER being in the chair.

Mr. PHILIP TURNER showed a case of Primary Chancres of the Lip in a male patient who was admitted to Guy's Hospital for an ulcerated swelling of the lower lip, which was first noticed eight weeks ago. The swelling, which was at first soft, rapidly increased in size, and in four weeks the skin broke and it commenced to discharge. About this time a second swelling appeared on the free margin of the lip. For two weeks the patient had complained of a sore throat. There had never at any time been any sore on the penis. When seen on Jan. 1st there was a round, raised swelling on the chin just to the left of the mid-line. In the centre of that was a circular ulcer about 1 in inch diameter, the base of which was composed of unhealthy-looking granulation tissue discharging thin pus. A second small indurated area, with slight ulceration, was present on the mucous surface of the lip at its junction with the skin. The submental, submaxillary, and cervical glands were enlarged but not tender, and the axillary glands were also palpable. There were ill-defined patches of a dull red erythematous rash on the chest and abdomen. Superficial ulcers with grey bases were present on both tonsils.

Dr. HERBERT FRENCH showed a case of Tumour below the Right Hypochondrium, ? Riedel's lobe. The patient, aged 34, was a married woman who had had six children, the youngest of whom was now 2 years old. She came to the hospital complaining of indeterminate symptoms, of which the chief were a feeling of being less strong than she was, a deficiency in her usual appetite, with a tendency to be sick in the morning. There were no symptoms directly referable to the abdominal tumour, which was only found as the result of ordinary routine examination. The woman had defective teeth, which probably accounted for her vague stomach symptoms; she looked strong and well. There was more than the usual degree of abdominal pigmentation, but that, she said, had been present for years. The patient had long had a tendency to constipation, but that had shown no increase of late. Extending down from beneath the right costal margin for a distance of 3½ inches there was a firm, painless, smooth tumour, more or less the shape and size of a goose's egg; it was external to the right mid-clavicular line and abutted upon the right flank, but did not extend backwards so as to fill up the loin. It could be grasped easily bimanually or by one hand when the fingers were behind and the thumb in front. It moved up and down with respiration, was dull to percussion, and the dulness over it was continuous with the hepatic dulness. There was no general enlargement of the liver. The lump seemed to be too much to the right to be a gall-bladder; it did not fill up the loin as a renal tumour or a suprarenal tumour would, besides which the urine contained no albumin, sugar, pus, or blood. The mass was smooth and permanent, and did not suggest from the feel of it that it was due to fæcal accumulation in the bowel or to a carcinoma of the hepatic flexure, and although the diagnosis was open to question the case was brought before the section as an example of a well-defined Riedel's lobe of the liver. There being no symptoms referable to the tumour, it seemed to require no treatment.

Dr. F. PARKES WEBER showed a case of Recurrent Aphasia with High Blood Pressure. The patient, aged 51, was admitted into the German Hospital on March 8th, 1910, having had eight attacks of slight temporary aphasia during the last seven weeks before his admission. Each of these attacks was accompanied by slight hemiparesis; in seven of them the paresis was on the right side, but in one of them on the left side. For six or seven weeks he had had headache, but there had been no vomiting or loss of consciousness. The patient was a well-nourished, intelligent man. He had slight optic neuritis, best marked in the right eye. The plantar reflex was of the extensor type (Babinski's phenomenon) in both feet, best marked in the left. The knee-jerks were active on both sides. The brachial systolic blood-pressure was 160 mm. Hg, and the radial arteries felt somewhat thickened. The urine was free from albumin and sugar, but a few tube-casts were detected by the centrifuge method. Nothing else abnormal was discovered. There was no history of syphilis. He was treated by iodide of potassium and had no further cerebral attacks. On April 10th, 1910, when he left the hospital, he said that all he had to complain of was slight headache in the morning. There had been no fever whilst he was under observation. The pulse had varied from 74 to 88 per minute. The daily quantity of his urine had averaged about 2500 c.c. He had increased somewhat in body weight. His brachial systolic blood pressure was 145 mm. Hg. Later on (in June, 1910) it was 150 mm. Hg. When seen again recently (Dec. 20th, 1911) the patient said he had had no further cerebral attacks and had not taken any medicine for a year. His only complaint was that attempting to work brought on a headache at the top of his head. Nothing abnormal could be discovered in his heart, lungs, or abdominal organs. His brachial systolic blood pressure was 140 mm. Hg. There was no paresis anywhere. The pupils were of medium size and reacted to light. Nothing abnormal could be discovered by ophthalmoscopic examination. The plantar reflexes were of the normal (flexor) type.

Dr. WEBER also showed a case of Chronic Splenomegaly of uncertain origin, with persistent leucopenia. The patient was a married Jewish woman, aged 23. Her spleen reached a good hand's breadth below the left ribs, but did not feel hard. Otherwise the patient appeared well, though rather pale. The history was that, after a confinement in August, 1910, she suffered from pains in the loins, headache, and giddiness. She had previously had no special illness; never malaria or jaundice. On admission to the German Hospital (Oct. 6th, 1910) she was found to have decided enlargement of the spleen, but beyond some abnormality in the blood nothing else abnormal was discovered. The red cells were 4,850,000 and the white cells only 2575 to the cubic millimetre of blood; the hæmoglobin was 80 per cent. On Oct. 30th, 1910, whilst under arsenical treatment, the patient was suddenly attacked with severe abdominal pain and vomiting, and, as there was likewise free fluid in the peritoneal cavity (shown by moveable dulness), the abdomen was opened by Dr. E. Michels. Nothing abnormal, however, was detected, excepting the presence of some ascites and enlargement of the spleen and liver; the capsule of the spleen was adherent to the surrounding parts; the peritoneum appeared extremely vascular. The patient recovered well from the operation and from the ascites, and left the hospital on Nov. 19th, 1910. Whilst in the hospital occasional moderate fever was observed. Wassermann's sero-reaction for syphilis gave a negative result, and von Pirquet's cuti-reaction for tuberculosis was likewise negative. A blood examination on Oct. 24th, 1910, gave: Red cells, 4,222,200 per c.mm.; white cells only 1200; hæmoglobin, 92 per cent. Differential count of white cells: polymorphonuclear neutrophiles, 27·4 per cent.; small lymphocytes, 44 per cent.; large lymphocytes, 11·3 per cent.; eosinophiles, 9·3 per cent.; transitionals, 7·3 per cent.; myelocytes, 0·7 per cent. Two nucleated red cells were seen. The white blood cells numbered 2680 on Nov. 19th, 1910, and 2650 on Jan. 2nd, 1911. A blood count in July, 1911 (when the patient was pregnant) gave: red cells, 4,660,000, and white cells 3500 in the cubic millimetre of blood. At this time the patient's disease might perhaps have been termed one of "anæmia splenica sine anæmia." In October, 1911, she lost much blood at her confinement. The most recent blood count gave the following figures: red cells, 3,922,000; white cells, 1975 per cubic millimetre of blood; hæmoglobin, 65 per cent. Differential count of white cells: polymorphonuclear neutrophiles, 68·3 per cent.; small lymphocytes, 14·7 per cent.; large lymphocytes, 4·6 per cent.; eosinophiles, 5·7 per cent.; transitionals, 6·7 per cent. Two normoblasts were seen during the count of 300 white cells.

Dr. WILFRED HARRIS showed two cases of Alcohol Injection of the Gasserian Ganglion for Trigeminal Neuralgia.[1]

Dr. H. E. SYMES-THOMPSON showed a case of Pulmonary Stenosis in a woman, aged 34, married, who enjoyed good health on the whole, and had had five children, including

[1] Dr. Harris's paper will be published in full in THE LANCET.

twins. She had noticed undue shortness of breath on exertion as long as she could remember and she complained of a certain amount of dyspepsia and constipation from time to time. Over the base of the heart there were a loud systolic murmur and a systolic thrill, which were most marked over the pulmonary area. The cardiac dulness was normal. There was no clubbing of the fingers, cyanosis, or anæmia, and no history of rheumatic fever, scarlet fever, or diphtheria.

Mr. C. H. FAGGE showed a case of Epithelioma of the Tongue; operation; subcutaneous recurrences on back five years later. The patient, aged 54, noticed a sore area on the dorsum of the right half of the tongue in 1892. During subsequent years it disappeared and recurred several times. Until 1897 he smoked about 4 oz. of tobacco in a pipe weekly; after that he reduced the amount. For two months before admission the tongue was ulcerated. In November, 1905, he sought admission into *Guy's* Hospital for indurated, raised ulcer, 1 inch in diameter, on the right half of the tongue; the left half of the dorsum showed chronic superficial glossitis; there were no palpably enlarged submaxillary or cervical lymph glands. The right half of the tongue with the submaxillary, salivary, and lymphatic glands were removed, and the patient was not seen again until December, 1911, when he complained of two hard, fixed masses on his back—one over the lower left ribs near the spine, and the other, the larger, on the right side; part of the latter was excised under local anæsthesia. Microscopically the lingual ulcer showed a typical squamous epithelioma; the lymph glands showed no secondary deposits. There was some difference of opinion as to the nature of the subcutaneous mass, and Mr. J. H. Targett had given Mr. Fagge his opinion that it was a secondary epitheliomatous deposit undergoing necrosis.

Mr. CYRIL A. R. NITCH showed a case of Supernumerary Mamma in a male aged 40, which was first noticed by the patient ten years ago. The breast was situated on the posterior fold of the axilla and the postero-internal surface of the upper arm on the right side. It was well formed and possessed a well-shaped nipple. The organ did not secrete any fluid.

Dr. H. C. CAMERON read a paper on the Relative Value of Immediate and Delayed Laparotomy in Pneumococcal Peritonitis. He said he had collected the cases of pneumococcal peritonitis admitted into Guy's Hospital during the last few years in order to attempt to estimate the effect of immediate laparotomy in that condition. He found that in many cases the diagnosis was correctly made. Pneumococcal peritonitis had characters which often distinguished it from peritonitis due to other causes. The age and sex of the cases collected were as follows:—

Females.		Males.	
No.	Age.	No.	Age.
1	27 years.	1	22 years.

Average, 9·3 years.		Average, 11·7 years.	

With regard to other pneumococcal infections, in 13 cases it was possible to say with certainty that there were other pneumococcal infections present at the same time. Of these, 12 died. One case, which certainly had lobar pneumonia also, recovered. In 12 cases there was no certain evidence of the infection of any other part; of these, 6 recovered and 6 died. Since the peritonitis was always the result of a pneumococcal septicæmia, the aspect of the patient and the type of respiration were sometimes those familiar in lobar pneumonia. Herpes labialis might be present and the onset might be with rigors or shivering. A high leucocyte count might be found. In four cases which Dr. Cameron had examined during the last few months marked ulceration of the colon was present, and the symptoms of colitis had preceded the onset of peritonitis by several days or even weeks. For example, one case was that of a young woman admitted to Dr. Hale White's wards on Nov. 11th. For four days she had had intermittent colicky abdominal pain. On her way home from work the pain suddenly became worse, and she was brought to hospital. Dr. Cameron was called to see her at 10 P.M. The temperature was 104° F., and her abdomen was rigid over the appendix. The abdomen was opened and the cæcum was found to be thick and œdematous. Its peritoneal coat was inflamed, and there was a little clear fluid, which escaped on opening the peritoneum. The appendix was healthy. In 30 hours the patient died, and within that space of time lymph had been poured out in such quantity that, at the necropsy, many pints were collected. The cæcum and ascending colon showed extensive follicular ulceration. The walls were œdematous and the lymphatic glands swollen and congested. In that case the operation took place within a few hours of the spread of infection to the peritoneum, and they were able to time the rate at which effusion of lymph took place. In several of the cases it was noted that early in the disease it was possible to detect the presence of fluid in the peritoneal cavity, and the presence of a massive effusion might be taken as characteristic of that form of peritonitis. In that case, too, the high temperature, 104° F., at the onset of peritonitis was to be noted. In one of the four cases with ulceration of the bowel the gut had actually perforated, and Dr. French, who did the post-mortem examination, was of opinion that that had occurred during life. Dr. Cameron could find no other record of such an accident. From a consideration of those points—the age and sex, the onset with rigors or herpes labialis, the evidence of preceding colitis, the simultaneous pleurisy, pericarditis, or pneumonia, the great and rapid exudation of fluid into the peritoneal cavity, the high temperature at the onset—it was often possible to make a diagnosis with some certainty. There remained the question to which he specially wished to draw attention—the advisability of submitting those cases to laparotomy at the onset of the symptoms. The peritonitis was always the result of pneumococcal septicæmia. The septicæmic process, if it did not end in death, would appear to run a course usually of some two or three weeks. When recovery did take place, one or more residual collections of pus were found; just as an empyema might complicate the convalescence of pneumococcal septicæmia with the more usual localisation in the lung. He had notes of four cases admitted to Guy's Hospital with such residual abscesses after recovery from the acute illness. One was in a woman, aged 27, who made a complete recovery on evacuation of the pus. Another was a boy, aged 10, who was admitted a month after the acute illness and who was discharged to a convalescent home with a diagnosis of tuberculous peritonitis. A year later he was readmitted in an emaciated condition with an abscess which had burst at the umbilicus, the pus from which was found to contain only pneumococci. Under vaccine treatment he made a good recovery. All four cases recovered without any complication. Such cases must suggest the possibility that recovery might take place without any operation at all. No proof could be given, but he offered the following as such a case of recovery without operation. He saw the child many times when it was under Dr. French's care. It was that of a girl, aged 15, who was admitted with vomiting and abdominal pain of two days' duration. The abdomen was swollen, rigid, and tender. In both flanks there was dulness, which shifted on rolling the child over. There was herpes labialis. The temperature was high, between 102° and 104° F., and the pulse was rapid. There was a leucocytosis of 15,600. The abdominal pain and vomiting ceased after four days, and the child made a good recovery. Dr. French diagnosed pneumococcal peritonitis. Cultivation from the herpetic vesicles gave a growth of staphylococcus albus. Such recovery, either with or without residual abscess, must be regarded as a rare and fortunate chance. If immediate laparotomy could claim to save even a small percentage of cases, there could be little doubt that it should always be advised. Dr. Cameron found that eight cases admitted in the acute stage were not operated upon before death. In seven of those pleurisy, pneumonia, pericarditis or endocarditis was present, as well as peritonitis. The eighth case died as soon as admitted. Twelve cases were submitted to immediate laparotomy. Nine of those died: four on the day following operation, the remainder

within a few days. Three cases recovered, but in all three the laparotomy performed at the onset of symptoms failed to produce immediate improvement. The patients passed through a long and critical illness, developed on convalescence the signs of abdominal abscess, and recovered after the evacuation of the pus. No case recovered without the formation of residual abscesses and without a second operation being required. It would appear that those cases of pneumococcal peritonitis which recovered were those which passed successfully through the pneumococcal septicæmia. After the termination of the acute septicæmia only a minority of cases died as a result of the failure to secure drainage of the residual collections of pus. That was, however, the cause of death in the case of a little girl, aged 11, who was admitted on Oct. 10th, 1911, with pneumococcal peritonitis, so ill that operation was delayed. She was almost comatose, with incontinence of urine and fæces. She improved greatly for three weeks, when a left subdiaphragmatic abscess was opened. Three further operations had to be performed to drain abscesses. After the last of those, unfortunately, a fæcal fistula formed, and the child gradually sank and died on Dec. 20th. For many weeks it seemed likely that she would recover. That she would have died at once if operated on on the day of admission was, he thought, certain. That was the only case he could find in which the policy of waiting was purposely adopted, but he thought that it was likely that in certain cases it was the right course to pursue. He could find no evidence that establishing drainage by laparotomy, at the onset of the disease, increased the chance of recovery from the septicæmia, or helped to cut short the process in the peritoneal cavity. On the other hand, he thought that there were cases so ill at the onset of the disease that laparotomy might turn the scale against recovery, and he suggested that in those cases it might be wiser to wait until the septicæmia was at an end, and until the disease had become local to the peritoneum, just as was done in dealing with the empyema which followed upon pneumonia. At the same time, he was fully conscious of the complexity of the problem and of the small help which statistics such as his could give in deciding the wisest course of action in any individual case.

SOCIETY OF MEDICAL OFFICERS OF HEALTH.

The Epidemic Grant and School Attendance.

A MEETING of this society was held on Jan. 12th, Professor A. BOSTOCK HILL, the President, occupying the chair.

Dr. WILLIAM BUTLER, in a paper on the Epidemic Grant and School Attendance, said that the withdrawal in 1903 of Article 101* of the Code of the Board of Education at once created difficulties for medical officers of health. The immediate consequence was that the education authorities were deprived of the special grant (which the Board was empowered to make in compensation for loss of actual grant) which would otherwise have been earned if the average attendance had been seriously diminished by what in effect was the advice of the medical officer of health in his attempts to control disease. The conflicting interests thus created had not yet been resolved, in spite of the efforts of the education authorities, who had suffered in purse, and the health officers, who had suffered in popularity. While the epidemic grant articles of the Code were in operation there was no organisation to meet the requirements of medical and health interests which those articles safeguarded. The medical officer of health was not an officer of the education authority, and with few exceptions no arrangement was in force whereby he could keep himself in touch with non-notifiable disease. His only information of the prevalence of, say, measles or whooping-cough was when he officially received the death returns. The epidemic grant was in effect an arrangement enabling the schools to earn their annual grant without diminution from loss of attendance due to the prevalence of infectious disease. Such a result was entirely unjustifiable. Designed as a measure for safeguarding preventive action, Article 101* worked in practice as an instrument of fatalistic non-interference. Not the steps to prevent the spread of disease but its actual prevalence was rewarded under the wrong-headed administration which made an epidemic of measles the ground for earning a grant. After referring to the withdrawal of the epidemic grant in 1903, Dr. Butler suggested that there should be instituted a health grant which should comprehend not merely the claims arising out of the procedure for dealing with epidemics but of all other considerations bearing upon the health of the children attending public elementary schools. A proportion of such a grant sufficient at least to cover the maximum loss due to interference with school attendance arising out of health considerations should be apportioned for this purpose, and should be paid only where the arrangements made for dealing with communicable diseases met with the approval of the Board of Education.

Mr. J. TUBB-THOMAS related his experience of the old epidemic grant and spoke of the many difficulties associated with it.

Dr. SIDNEY DAVIES deprecated the action of school attendance officers and of teachers in urging children to attend school when not in a fit state of health. He considered there was not the need for attendance officers which prevailed in former years.

Dr. W. J. HOWARTH considered that the ordinary grant should be based on general grounds and should not depend on individual attendances.

Dr. A. H. BYGOTT deprecated the giving of prizes for regular attendances. As a result many children went to school when they should remain at home. He spoke approvingly of the appointment of women attendance officers.

Dr. J. M. CLEMENTS and Dr. W. A. BOND regretted the withdrawal of the epidemic grant.

Dr. R. DUDFIELD had found the grant extremely useful, though it suffered from the fault that it paid for sickness rather than for health. He thought it a pity the medical officers of health in London were not more in touch with school work.

Dr. H. FRANKLIN PARSONS pointed out that when the epidemic grant was withdrawn it was thought the money saved could be more usefully spent in other directions. He remarked that with the advent of systematic medical inspection there was not the same difficulty as formerly in ascertaining whether a child was really ill or not.

Dr. P. CALDWELL SMITH considered that the grant in its day did good, but thought there would be little need for any grant at all if children were not admitted to school under six years of age.

Dr. JAMES KERR said that the epidemic grant was intended to be an insurance against infectious disease, and as such it acted very well. It had the effect of preventing children being improperly crowded into the schools by teachers and attendance officers.

Mr. E. H T. NASH felt sure there was no likelihood of the epidemic grant being introduced, and hoped that Dr. Butler's proposal would be pressed forward.

Dr. GERARD C. TAYLOR was of opinion that already there was ample power to exclude children from school attendance for such periods as the medical officer of health thought fit.

The PRESIDENT pointed out that the introduction of medical inspection had complicated the position. He spoke with approval of the institution of a general health grant for large towns, but feared it would not be applicable to rural areas.

LIVERPOOL MEDICAL INSTITUTION.

Rational Treatment of Chronic Suppurative Otitis Media.—Diagnosis and Treatment of Gastro duodenal Ulceration.

A MEETING of this society was held on Jan. 11th, Dr. T. R. BRADSHAW, the President, being in the chair.

Mr. C. A. ADAIR DIGHTON read a note on the Rational Treatment of Chronic Suppurative Otitis Media. This he considered to be the immediate treatment by means of Heath's conservative mastoid procedure in every case uncomplicated by labyrinthine suppuration when first seen. Mr. Dighton reviewed the tremendous advantages of this operation in regard to the restoration of hearing, and contrasted it with other recognised methods of treatment. All of these he considered unsatisfactory, and further was of opinion that the radical operation was unjustifiable except in cases

of labyrinthine suppuration. He considered that by Heath's method the hearing was restored in 75 per cent. of cases, and reported instances in support of this. In one case the patient from inability to hear a watch on contact had improved after the operation so much that he could hear it at 17 inches, which was the normal for that watch.—Mr. THOMAS GUTHRIE said that the so-called Heath's operation was in principle identical with that introduced by Kuster in 1879 and abandoned both by himself and other otologists as a routine operation for chronic disease. Its proved inadequacy for a majority of chronic cases in which the tympanic structures were seriously diseased led to the evolution of the radical operation. For suitable cases, however, the operation was a good one, but these cases were a small minority. Mr. Dighton advised resort to the partial mastoid operation in all cases of chronic suppurative disease, yet it was a matter of common knowledge that in large numbers of these cases healing took place after such measures as removal of adenoids and various forms of intrameatal treatment.—Mr. E. MALCOLM STOCKDALE regretted that Mr. Dighton had dealt with the subject from such a narrow point of view, and emphasised the importance of distinguishing sharply between acute and chronic cases. He agreed with Mr. Guthrie as to the importance of removing adenoids if present. Concerning mastoid disease, the anatomical structure of the mastoid portion of the temporal bone was of the greatest importance. When the antrum communicated freely with air or marrow cells mastoiditis ensued early, and required a post-aural operation. In these cases Mr. Stockdale performed the conservative mastoid operation. When the mastoid antrum had a firm, bony wall, and was small, a post-aural operation was only likely to become necessary in neglected cases, and here the radical or complete post-aural operation was called for. Speaking from a long experience of this operation in this class of case, Mr. Stockdale had usually found the tympanum damaged beyond the hope of useful repair, the malleus, incus, or both, being frequently missing, the incus usually being shed before the malleus. The Eustachian tube should receive attention. In the few exceptional cases of chronic suppurative middle-ear disease where spontaneous arrest of the discharge took place, the ear was commonly rendered very deaf. He could not accept the statement that the operation damaged the hearing in these cases, as by careful observation he had usually found that it resulted in a considerable improvement.—Mr. HUGH E. JONES congratulated Mr. Dighton on his results, but remarked on several fallacies which occurred in his note—e.g., the assumption that the antrum was always diseased in suppurative otitis media; the antrum might be the reservoir for pus or its lining membrane might be inflamed in the early cases, but in the genuinely chronic cases the real bone disease was generally in the tympanum. The statement that the radical mastoid operation destroyed the hearing was not in accord with facts; the resulting state of the hearing whatever operation was performed depended upon the condition of the essential organs before operation. He had done from one to two hundred modified operations in selected cases, but he found that in many of them further and more radical operations had to be performed afterwards.—In reply, Mr. DIGHTON pointed out that Heath's operation was not the same as Kuster's.

Mr. KEITH W. MONSARRAT read a paper on the Diagnosis and Treatment of Gastro-duodenal Ulceration, with an analysis of 50 consecutive cases of simple affections of the stomach submitted to operation. The series included 18 cases of gastric ulcer not at the pylorus, 11 cases of duodenal ulcer, 15 cases of pyloric and duodenal stenosis, and 4 cases of gastric dilatation without stenosis. He tabulated the nature and result of the operation and discussed the differential diagnosis.—Mr. F T. PAUL was not in favour of excising ulcers of the stomach and did not consider the results of gastro-enterostomy very satisfactory for ulcers far removed from the pyloric region apart from hour-glass contractures. On the other hand, pyloric and duodenal ulcers and stenosis were most satisfactorily treated by gastro-enterostomy. He had very slight experience of any ulterior undesirable conditions except such as were directly due to inexcusable faults on the part of the patient Mr. Paul laid stress upon the desirability of closing the pylorus by a silk purse string suture in cases of duodenal ulcer, and it was of especial importance to do this in cases of perforation. He recommended gastro-enterostomy to be done whenever possible in such cases.—Mr. G. P. NEWBOLT considered that the diagnosis between gall-stones and gastro-duodenal ulcer was often most difficult. He had met with a combination of the two diseases. He quoted a case of posterior gastro-enterostomy which was performed for duodenal stenosis and in which the patient died 18 months later from hæmorrhage due to ulceration around the gastro-enterostomy. He believed that a good number of people died directly from hæmorrhage from gastric and duodenal ulcers, although they were led to believe that this was rarely the case. He performed the posterior "no loop" operation, but was not in favour of performing this operation when closing a perforated duodenal ulcer, preferring to do it later if required.—Mr. ARTHUR J. EVANS emphasised the frequency and danger of duodenal ulcers. He had been called upon to operate no less than seven times within the last 12 months for the condition. He questioned the desirability of doing gastro-enterostomy at the time in addition to closure of the perforation and invagination of the ulcer. He had had five recoveries out of the seven in which simple closure had been done. There were both severe shock and peritonitis in these cases, and the addition of gastro-enterostomy under these circumstances would, he thought, add a great risk.—Dr. P. F. TINNE called attention to the great similarity between cases of Henoch's purpura and gastric ulcer with sudden symptoms of perforation. In both there were hæmatemesis, sudden violent abdominal pain, and to all appearances the classical symptoms of perforation. It was not till the following day that the purpuric spots about the joints made their appearance and settled the diagnosis.

EDINBURGH OBSTETRICAL SOCIETY.

Pyosalpinx.

A MEETING of this society was held on Jan. 10th, Dr. J. HAIG FERGUSON, the President, being in the chair.

The PRESIDENT read notes on a case of Pyosalpinx successfully removed by abdominal section during the puerperium. The patient was pregnant with her second child when she experienced pain in the left side during her fifth month of pregnancy. It increased in degree and became almost constant until labour set in. On the sixth day after labour there was severe pain in the left iliac fossa, though her temperature had been raised for three days. On vaginal examination the only abnormality to be detected was a soft, round, exquisitely tender swelling, about the size a small plum, in the left lateral fornix, moveable apart from the uterus. For some days the temperature continued raised and the swelling was observed to have become more diffuse with thickening and fixation of the surrounding parts. After waiting for the subsidence of the more acute symptoms, on the seventeenth day of the puerperium the President operated and found a left pyosalpinx with considerable adhesions in the neighbourhood. Owing to the escape of pus and the presence of a considerable oozing area, drainage by the vagina was decided on. The patient made a satisfactory recovery. The purulent contents of the tube were found to yield a mixture of streptococcus pyogenes and staphylococcus pyogenes aureus. Chronic inflammation was observed in sections of the tube. There was no history of gonorrhœa at any time. It was a point of interest that though the patient had suffered pain from the fifth month of pregnancy and the tube showed signs of chronic inflammation yet she showed no acute and severe symptoms until the fifth day after labour, and the probable explanation was given by the late Dr. R. Milne Murray when he ascribed it to some subtle change in the vital processes or tissue metabolism which follows the passage from the state of pregnancy to the state of the puerperium. In distinguishing a tubal condition from a cellulitis a guide was the height of the swelling in the broad ligament as determined by bimanual examination. The higher it was the more likely was it to be tubal or mainly tubal, though subsequent extension of inflammation might obscure this If the swelling began in the base of the broad ligament and extended upwards and outwards, it was a cellulitis, probably the result of an infection from a cervical tear. The bruising during labour or twisting of a small ovarian cyst might be mistaken for a tubal condition. A blood examination did not give much assistance unless the leucocytosis rose very rapidly.

Dr. A. H F BARBOUR stated that only by abdomina section could one arrive at a certain diagnosis. If the

condition in this patient had continued from mid-term, how did symptoms develop in the puerperium? It was evident that a tubal condition must have begun before pregnancy. The other probability was a septic infection during the puerperium. As regards differential diagnosis he had seen many cases of cellulitis begin high up in the broad ligament and extend along the round ligament and also downwards. The bacteriological report pointed to a recent suppuration in the tube; if it had been an earlier infection he would have expected the pus to be sterile.

Dr. J. LAMOND LACKIE referred to a case which he had seen with Dr. Milne Murray, where the chief feature was the absence of physical signs, nothing being felt through the abdominal wall or in the fornices. As the patient was very ill the abdomen was opened, and an inflamed tube was found from which a very small amount of pus was squeezed out at the abdominal end, which was not closed. The patient's urgent symptoms were immediately relieved.

Dr. F. W. N. HAULTAIN said there should not be much hesitation in opening the abdomen during the puerperium. Some were apt to consider it dangerous. He had opened the abdomen several times during the puerperium, and all the patients had done well. The main feature in pyosalpinx in the puerperium was its mobility and high situation; if there was cellulitis in the broad ligament the mobility was not so great. He would not be inclined to wait so long as the President before operating.

Dr. JAMES RITCHIE raised the question whether in a case of tubal disease recognised during pregnancy it would not be better to operate during the pregnancy as the condition might become worse owing to injury during labour, and after labour there was much more risk of infection.

Dr. B. P. WATSON instanced a case of double pyosalpinx beginning after delivery. The patient was quite well until the tenth day, when her temperature was raised and pulse quickened. Her symptoms were fairly acute for a week, and two cystic swellings, tender and movable, were found in the lateral fornices. The infant developed ophthalmia, and gonococci were found in the discharge from the eyes. It was thought better not to operate in the acute stage. On waiting the patient improved so much that in one month she was perfectly well, all signs of swelling in the tubes having quite disappeared. She had been delivered of another child since then.

Dr. JAMES YOUNG reported a case of pyosalpinx developing one month after a two months' abortion. The patient was operated on four weeks after it began, and the pus in the tube was then found to be sterile.

Dr. N. T. BREWIS said the question was when to interfere. He had found cellulitis an exceedingly rare affection in the puerperium; the swellings were more frequently tubal. There would be no hesitation if one could be sure the condition was sterile. Some required interference, but the majority got well if they were left alone. The proper route for operation was in early cases by opening the abdomen, as the adhesions were not dense and were easily separated, and there was not much chance of infection from the escaping pus. In older cases the vaginal route should be chosen if the tube was fairly adherent, as the adhesions could be more easily separated and the operation more safely accomplished from below. The pus in cases of pyosalpinx became sterile after a time, but there could be a reinfection.

The PRESIDENT, in reply, stated that a swelling in the fornix high and movable was probably tubal. As to the question of operation during pregnancy, the difficulty was the diagnosis, and it was known that operations during pregnancy after the fourth month were apt to be followed by premature labour.

Dr. D. BERRY HART read a paper on Numan, the veterinarian and comparative anatomist of Utrecht, a forgotten observer on the freemartin. Numan's atlas and text were shown and the circumstances of the rediscovery of their existence explained.

WEST LONDON MEDICO-CHIRURGICAL SOCIETY.—A clinical meeting of this society was held on Jan. 5th, Mr. W. McAdam Eccles, the President, being in the chair.—The following cases were shown:—The President: 1. Gummatous Infiltration of the Thigh in a man with no specific history. The patient first noticed a small, hard lump in Scarpa's triangle on the right side; this gradually increased, apparently invading the sartorius sheath, and tracking down to the insertion of the muscle. X rays threw no shadow. On the shin of the right leg were two typical specific patches, and Wassermann's reaction had been positive twice. He was improving under mercury and iodide. 2. Transposition of Viscera in a man. This was a case of complete transposition, including the attachment of the mesentery. The patient had come for treatment for vomiting and hæmatemesis and had a posterior gastro-jejunostomy performed; during the operation it was possible to demonstrate the completeness of the transposition. It was interesting to note that the man was right-handed.—Mr. W. E. Fry: A patient with Two Big Toes on one Foot, with skiagrams.—Dr. T. Grainger Stewart: 1. A case of Myotonia Atrophica in a male aged 39. The wasting involved the sterno-mastoids, biceps and triceps, forearm muscles, and slightly the small hand muscles; also the thigh muscles and muscles below the knee. The patient was unable to close his eyes tightly or to smile. 2 A case of Tremor of the Right Hand on sustained voluntary movement in a male aged 12 A history of headache and vomiting and presence of optic neuritis made clear the presence of intracranial pressure. Corroborative tests had not yet proved the lesion to be tubercular, the seat of the lesion probably being in the hypothalamic region on the left side. 3. A case of Bilateral Involuntary Movements in a male aged 9½. This case was a seven months child; he made no attempt to use his hands until the age of 3, and was unable to walk until the age of 7. He taught himself to write and to feed himself with his toes before he learnt to walk. Involuntary movements were first noticed at the age of 4; these had gradually increased; no fits. There were present athetoid movements of both arms and of facial muscles, much increased by any voluntary innervation—e.g., talking or attempting to move the arms; no spasticity; voluntary movement was almost absent in the arms. Sensation was unimpaired.—Dr. F. G. Crookshank (for Dr. J. M. Bernstein): A case of Cretinism with a goitrous mother. The interesting point in this case was that the child was born in Ealing, the mother in Bethesda in Wales, where endemic goitre was said to occur, and she had an enlarged thyroid. In the Swiss valleys the endemic cretins were born of goitrous parents.—Dr. Arthur Saunders: A case of Subcutaneous Rheumatic Nodules in a child aged 4. This case was shown at a previous meeting of the society, and was again brought up to show the changes in the nodules. Some had completely disappeared, whereas some had increased in size. Photographs taken when the child was shown some three months back and some taken recently showed well the changes mentioned.—Dr. Phineas S. Abraham (for Dr. H. J. Davis): A case of Sessile Papillomata of the Palate, and a case of Lupus of the Larynx.—Mr. Aslett Baldwin: A case of Fracture Dislocation of the Left Elbow treated by operation, and a case of Ruptured Left Tympanic Membrane and Facial Paralysis.—Mr. R. B. Etherington-Smith: A case of Gumma in the Left Biceps Muscle with Paralysis of Muscles of Left Shoulder Girdle.

UNITED SERVICES MEDICAL SOCIETY.—A meeting of this society was held at the Royal Army Medical College on Jan. 10th, Major E. B. Waggett, R.A.M.C. (T.), the President, being in the chair.—Lieutenant-Colonel C. H. Burtchaell, R.A.M.C., delivered a lecture illustrated by magic lantern slides on "The Medical Service with Lord Methuen's Force in the Advance on Kimberley in 1899, with Reference to the Modern Organisation of the Medical Service." Colonel Burtchaell first compared the organisation of field ambulances with that of the bearer companies and field hospitals they had replaced. He showed that the only essential differences were that the former were now divisional units, that the bearer and hospital *personnel* now formed part of one unit which was divisible into three parts, and that while there was an increased number of stretchers and stretcher-bearers under the new arrangement the *personnel* available for dressing stations and so-called hospital purposes was practically the same as formerly in relation to the strength of troops, one tent subdivision of a field ambulance being almost identical with half of a field hospital. He then described in detail the work of the medical services at the four battles which occurred during the advance on Kimberley. Among many interesting points which came out the following were specially noteworthy. The principal medical officer was present at the staff reconnaisance before the battle of Belmont, and, thus made acquainted with the plan of action and the ground, he was able to select places for the dressing

stations, &c., and to forecast the arrangements for succour of the wounded much more effectively than if he had had to rely on second-hand information. At the Modder River the medical units were following close behind the troops when the enemy unexpectedly opened a heavy fire. This determined the position of the dressing stations which were located just out of range of the ememy's guns or in the nearest dead ground available. Ambulance wagons were unable to reach the regimental aid-posts where wounded were collected until after nightfall, when the enemy withdrew. At the battle of Magersfontein the field hospitals accompanying the troops were held in reserve during the first stage of the engagement, and did not open until late in the day, when they moved up to the sites of the dressing stations formed by the bearer companies. One field hospital—i.e., the equivalent of two tent sub-divisions of a field ambulance—remained at Modder River, four miles distant, and there received and entrained over 600 wounded for Orange River and Cape Town. At Orange River difficulties arose because there was no organisation like their present clearing hospital available at that place.—Surgeon-General Sir James Porter, K.C.B., R.N. (who was with the Naval Brigade under Lord Methuen's command), discussed various points mentioned in the lecture and spoke in high terms of the work which the Army Medical Service did during the operations which had been described.

BRIGHTON AND SUSSEX MEDICO-CHIRURGICAL SOCIETY.—A meeting of this society was held on Jan. 4th, Mr. T. H. Ionides being in the chair.—Mr. H. H. Taylor showed a man aged 35, who had complained of failing sight which he had noticed for a few weeks. On examination, vision in the right eye was 6/36, and in the left eye 6/6. The right disc was distinctly white, with clean-cut edges, and normal vessels. The left was pale, but not atrophied. Later a perimetric examination was made, and it was found that in the right eye there was a very restricted area of vision in the temporal field, and no central vision at all. In the left field there was temporal hemiopia. The pupils were so contracted that it was not possible to get Wernicke's sign. There was no tremor or ataxia, and the knee-jerks were normal. There was no sign of acromegaly, and an X ray photograph showed no enlargement of the sella turcica.—Dr. D. G. Hall read notes and showed photographs of a case of Henoch's Purpura in a boy aged 15. The illness began with pyrexia and general pains. The eruption appeared next day on the limbs and gastro-intestinal symptoms a day later. These consisted of hæmorrhage from the bowel, vomiting, and severe abdominal pains. A week later both eyes were occluded by a serous effusion which cleared off in a few days. Three weeks from the initial symptoms he developed a mitral systolic bruit and marked irregularity of pulse. At the same time blood and casts appeared in the urine. At the height of the attack he passed about a dozen stools with some blood in them each day, and from time to time there were various joints affected. Treatment was mainly dietetic and symptomatic, and after some months the boy left Brighton, having made an incomplete recovery.—Dr. L. A. Parry read notes of some cases of Urinary Calculi. He advocated the suprapubic operation in boys unless the operator had had very considerable experience of lithotrity. In women dilatation of the urethra and extraction of the stone was the ideal procedure, and was available for stones up to about 1½ inches in diameter. He referred to a case of a stone in the female bladder, which had formed round a hairpin used for the purpose of procuring abortion. The sharp ends of the pin, which were not covered by the stone, were seized with Spencer Wells forceps and the stone easily withdrawn. A case of stone in the urethra, which gave a negative result with an X ray photograph, but was detected by means of the cystoscope, and subsequently removed, was also recorded.

GLASGOW OBSTETRICAL AND GYNÆCOLOGICAL SOCIETY.—A meeting of this society was held on Dec. 13th, 1911, Dr. A. W. Russell, the President, being in the chair.—Dr. William Ritchie read notes of a case of Stone in the Bladder, with early recurrence. The recurrence took place ten months after cystotomy had been performed. He thought this was due to the site of the calculus not having been sufficiently curetted after removal of the stone. After the first operation the repair of the fistula was not satisfactory; this he attributed to the fact that the fistula had been immediately closed, and that the accompanying cystitis had not been cured by prolonged drainage, as was done at the second operation.—Dr. Nigel Stark read a paper on Uterine Fibrosis and Allied Conditions, with Special Reference to Treatment. He pointed out the want of a standardised and universal nomenclature in gynæcology and the confusion that resulted. Many text-books made no mention of the term "fibrosis," but attributed all the symptoms now ascribed to it to chronic endometritis. By fibrosis was meant increase of fibrous tissue or replacement of muscular by fibrous tissue. It was always accompanied by increase in the size of the uterus. The enlargement might be slight, and on dilating the cervix hardly any mucosa came away on the curette. The clinical features were hæmorrhage, leucorrhœa, dysmenorrhœa, and pain. As regards treatment, removal of the ovaries was recommended by some, but hæmorrhage was not always arrested after this had been done. Hysterectomy had therefore come to be the operation of selection. He considered this too drastic, and advocated the excision of a wedge-shaped portion of the body of the uterus. This operation, "uteroplasty," he had performed on eight occasions.—Dr. G. Balfour Marshall preferred hysterectomy as hæmorrhage had recurred after uteroplasty.—Dr. A. C. McIlroy condemned the removal of the ovaries.—The President said he treated this condition by vaginal hysterectomy.—Dr. A. MacLennan showed a special Instrument for Closing the Utero-vesical Pouch in Ventro-fixation.—Fresh specimens were shown by Dr. McIlroy, Dr. D. Shannon, Dr. Balfour Marshall, the President, and Dr. Nigel Stark.

Reviews and Notices of Books.

Man and Beast in Eastern Ethiopia. By J. BLAND-SUTTON, F.R.C.S. Eng. London: Macmillan and Co., Limited. 1911. Pp. 419. Price 12*s.* net.

THOSE of our readers whose minds can carry them back some 45 years will remember the interest and excitement with which the publication of Sir Samuel Baker's "Albert N'Yanza" was received, and the difficulties and hardships of his journey. Nowadays, however, Uganda and the Uganda Protectorate are so within the bounds of civilisation that they are available for what may be called holiday tours, and Mr. Bland-Sutton's book deals in part with such a tour. Roughly speaking, his travels extended over a district ranging between 5° north and 2° south of the equator, and from Mombasa as far as 30° east, although large portions of this area were naturally left untouched. Starting from Mombasa, he, in company with Dr. Comyns Berkeley, journeyed by the Uganda Railway to Port Florence on the north-western shore of the Victoria Nyanza. Thence they travelled about on the northern shore of the lake and returned by caravan through the Rift Valley, a portion of which is traversed by the railway. Mr. Bland-Sutton gives a vivid, if somewhat impressionistic, description of the various tribes with whom he came into contact, and of the fauna and flora, together with some remarks upon the geological features of the country. Written by one who, though a trained observer, with a wide range of scientific knowledge has done no special work in natural history, the book is of very great interest to non-technical readers, and this interest is enhanced by the admirable illustrations. Some of the observations upon the curious fashions in ear ornaments among the Kikiyu and neighbouring tribes have already appeared in our columns.

The portion of the book which appeals with most novelty is the description of the great Rift Valley, a mighty depression which Mr. Bland-Sutton considers is to be comparable only with the great cañon of the Colorado River in Arizona. The Rift Valley, however, unlike its American congener, exhibits various evidences of volcanic activity in the shape of hot springs, steam holes, and the like

and the valley abounds in bird and animal life. Other chapters are devoted to an account of the various tribes, their dress, manners, and customs, and in addition the fauna and flora are described under the headings of lions, crocodiles, thorns, horns, antelopes, gazelles, beaks, crests, tails, wings, jiggers, ticks, mosquitoes, and flies and sleeping sickness. There is also a chapter upon ivory, which Mr. Bland-Sutton considers, and we think rightly, as "one of the greatest curses of Africa."

Although Mr. Bland-Sutton writes in no way as an explorer, there is a good deal of matter in his lively account of his travels which will be new even to those who have read many reports and books published by other writers and explorers; and those of our readers who will feel stimulated by Mr. Bland-Sutton's account to inquire further into the features of the country will owe him a debt of gratitude for the bibliography given at the end of each chapter, containing the names of works written by experts on the various subjects with which the chapters deal.

Dental Disease in its Relation to General Medicine. By J. F. COLYER, L.R.C.P. Lond., M.R.C.S. Eng., L.D.S. R.C.S. Eng. With the assistance of STANLEY COLYER, M.D. Lond., M.R.C.P. Lond., D.P.H. London: Longmans, Green, and Co. 1911. Pp. 189. Price 4*s.* 6*d.* net.

THIS interesting little book sets out in clear style the relationship that exists between dental and oral and general diseases. The information is badly needed. But scant study is given by the ordinary medical student during hospital work to the mouth and its contents, and afterwards he is inclined to consider their affections unworthy of his earnest consideration. He sedulously treats general systemic disease, but frequently fails to recognise the importance which attaches to oral hygiene. The authorities of the sanatoriums of this country cannot likewise be excluded from the same criticism. Patients are daily lying in the wards of our hospitals whose mouths are in the filthiest condition with obviously grave effects. This book draws earnest attention to the surgical requirements of the mouth and of the teeth, and being written by persons of acknowledged authority its publication should certainly do great good.

Of course, there is a danger lest things which have for years needed saying, when they come to be said, should be said too forcibly. In certain quarters during the last decade the oral cavity has been regarded as a veritable hot-bed of infection—a focus of disease eventually menacing the health and at times the life of its owner. We find this to be an extreme view, and therefore regret that two such experienced and close observers as the authors of this work—especially in the later of the pages before us and in those dealing with "Oral Sepsis and its Influence on the Body"—should appear to adopt it. The evidence adduced to prove that "oral sepsis" is the cause of neurasthenia, cardiac irregularity, "subacute combined degeneration of the spinal cord," infective endocarditis, and other things, is suggestive but not convincing, and perhaps the same might be said of its close association with pernicious anæmia. The authors have spared no pains to collect cases and to narrate the opinions of other writers, but they have not been able to draw convincing conclusions. The entire subject, which is of the utmost importance to the public as well as the medical man, cannot be dealt with within the compass of a small manual; and this has hampered the authors, who would no doubt have preferred to write at far greater length and with full justifying details. It is probably right to believe that gastritis and some of its sequelæ resulting from severe "oral sepsis" are due to the ingestion of pathogenic oral bacteria, but gastric ulceration, for example, cannot yet be definitely attributed to the same cause, and the same must be said of secondary pancreatitis and parotitis. Oral sepsis includes, say the authors, "all chronic inflammatory diseases about the mouth," and the reservation apparently made with regard to what is known as pyorrhœa alveolaris is clearly accidental, for the description given of the condition shows it also to be an oral sepsis. There is a good deal of ambiguity in connexion with the use of the freely-recurring term "periodontal disease," and it is difficult precisely to define its meaning.

It will be gathered that we think that the authors have claimed too much mischief as traceable to the neglected or diseased mouth, but none the less we can recommend their book warmly to the practitioner. It is becoming daily more evident that he should be particularly interested in dental (and oral) disease, whether engaged in the general practice of medicine or as a consultant following some special branch. The wholesale extraction of teeth as opposed to their proper preservation and the due observance of oral hygiene is a serious matter, and as the procedure is growing in popularity the profession ought to consider the logicality of the arguments upon which it is founded.

Diseases of the Nose, Throat, and Ear, Medical and Surgical. By WILLIAM LINCOLN BALLENGER, M.D., Professor of Otology, Rhinology, and Laryngology, College of Physicians and Surgeons, Department of Medicine, University of Illinois. Third edition, revised and enlarged. Illustrated with 506 engravings and 22 plates. London: Henry Kimpton; Glasgow: Alexander Stenhouse. 1911. Pp. 983. Price 28*s.* net.

Professor Ballenger's text-book on diseases of the throat, nose, and ear has reached its third edition, and within three years. The publisher's note states that "the phenomenal demand for three large editions of this work in much less than three years is explained by its combination of utility, completeness, and high authority." Many text-books, as distinct from monographs of original research, are like directories, inasmuch as they hold good only for the year in which they are published. The author in his preface informs us that the general purpose of the work is not changed. It was designed as a text-book for students, as a guide for practitioners, and as a book of reference for the specialist. The contents are no less comprehensive than the general purpose of the work. They include the medical as well as the surgical treatment of the diseases in the entire region of the nose, throat, and ear.

As the text-book has arrived at its third edition, it is necessary to mention only a few of the more important new features which have been introduced. Amongst these we notice a description of a plastic operation for the closure of a recent perforation of the septum of the nose. Briefly stated, in the words of the author, the operation is as follows: "When both mucoperichondria are torn during a submucous operation, thus making it probable that a permanent perforation will follow, the cartilage removed may be reintroduced between the membranes, and thus afford a bridge over which the granulating edges of the mucous membranes may extend and close the perforation." At the meeting of the British Medical Association held at Birmingham last year a paper was read in the Section of Laryngology, Otology, and Rhinology on the Submucous Resection of the Nasal Septum. In the discussion which followed upon the paper more than one speaker expressed the opinion that a perforation of the septum could not be looked upon as a tragedy or disaster.[1] In view of these opinions and also in view of the opinions at times expressed that the perforation of a septum obstructing the nostrils is a distinct advantage to the nose as an organ of respiration, it would seem that this operation for closing a perforation of the

[1] THE LANCET, August 19th, 1911, p. 514.

septum following upon the operation of the submucous resection of the structure is a work of supererogation. Certainly anxiety resulting from the perforation of the septum in the course of an operation to relieve distressing nasal obstruction should be considered unnecessary.

This edition of Professor Ballenger's work shows the prominence achieved by vaccine therapy in the treatment of infectious diseases of the accessory sinuses of the nose, ear, throat, and meninges. In previous editions mention of Vincent's angina has been absent but the subject is now included. The chapter dealing with foreign bodies in the larynx, the trachea, the bronchus, and the œsophagus has been revised by Dr. Chevalier Jackson, whose work and experience in this department of the specialty are well known. In the section dealing with diseases of the ear the functional tests of the vestibular apparatus have been revised by Dr. J. R. Fletcher, and the section on labyrinthine disease and its surgical treatment has been largely rewritten.

We have no hesitation in congratulating Professor Ballenger upon the success of his labours and in endorsing the remark made in his preface that his effort has been to reflect the high character of work being done by laryngologists and otologists all over the world.

Surgery of the Genito-urinary Organs. By J. W. S. GOULEY, M.D. London: Rebman, Limited. New York: Rebman Company. Pp. 531. Price 8*s.* net.

WHEN the medical student becomes qualified and enters on the practice of his profession he finds often that there are departments of surgery in which his knowledge does not come up to his requirements, and he has to supplement it in one way or another. It is perhaps in the diseases of the genito-urinary system that he feels the chief need for more information than is contained in the text-books employed for the purpose of passing his examinations, and for this purpose he cannot have a more convenient book than that before us. It is not too lengthy, and yet it contains all that the average practitioner is likely to want. In it are to be found many of those hints and points which are so valuable in the routine of practice, and yet are so rarely to be found within the covers of a manual. The author's style is easy and readable, and the numerous references to the history of the subject serve to enhance the interest of his work.

Lehrbuch der Chirurgie. Bearbeitet von Prof. KLAPP, Berlin; Prof. KÜTTNER, Breslau; Prof. LANGE, München; Prof. LANZ, Amsterdam; Prof. PAYR, Königsberg; Prof. PERTHES, Tübingen; Prof. POPPERT, Giessen; Prof. PREYSING, Cöln; Prof. DE QUERVAIN, Basel; Prof. J. RIEDINGER, Würzburg; Prof. RITTER, Posen; Prof. ROVSING, Kopenhagen; Prof. SAUERBRUCH, Zürich; Prof. SCHLOFFER, Innsbruck; Prof. TILMANN, Cöln; Prof. WILMS, Heidelberg; Prof. WULLSTEIN, Halle. Herausgegeben von Prof. WULLSTEIN und Prof. WILMS. Second revised edition. In three volumes. Vol. I., pp. 636. Vol. II., pp. 482. Vol. III., p. 602. Jena: Gustav Fischer. Price marks 28.50.

LESS than three years after the appearance of the first edition of this work a second edition has been required; this fact is in itself a proof of the value of the work and its appreciation by the medical public both of German-speaking countries and of other lands. Even in the short interval that has elapsed since the issue of the first edition many important changes have been made in surgery, and the editors have had the work revised so far at least as the short time allowed.

The trustworthiness of such a system of surgery is assured by the names of the contributors, and we may say that the quality of the product is fully equal to what might have been expected. The work is extensive, as may be gathered from the fact that it contains some 700,000 words, but even into so great a space as that it is difficult to compress the whole of surgery, so that here and there we cannot help wishing that a subject might have been treated more fully. We are not complaining of what is given, but we appreciate it so highly that we should like to have more. In a work of this character there must necessarily be numerous subjects on which differences of opinion exist, but a full discussion of these would require an immense amount of space, and, moreover, we must acknowledge that the authors have been very moderate in their articles, and that prominence is given to the various views that are held by different authorities. The illustrations are very good; for the most part they have been taken from photographs of cases, and the reproductions have been successful. The work is in every way a worthy product of German science.

Allen's Commercial Organic Analysis. Volume V. Fourth edition, entirely rewritten. Edited by W. A. DAVIS, B.Sc., A.C.G.I., and SAMUEL S. SADTLER, S.B. London: J. and A. Churchill. 1911. Pp. 704. Price 21*s.* net.

THIS volume deals with a very important group of commercial substances—viz., the tannins, leather, dyes and colouring matters, and inks. Mr. W. P. Dreaper contributes the interesting monograph on tannins, and his intimate acquaintance with the subject is evident from the references to the original work which he has contributed from time to time, chiefly in analytical directions. This section contains a valuable series of tables, and some idea of the multiplicity of tannins is furnished in the fact that no less than nine tables are devoted to recognition tests. The same author contributes the section on the analysis of leather, and it is interesting to note that he includes a water-penetration test and a water-absorption test. "Good sole leather," we are told, "takes about 170 to 250 hours" for water to penetrate it when the experimental piece of leather is tested under conditions described.

By far the larger portion of the volume is devoted to dyes and colouring matters, and if we include the special article on colouring matters in foods no less than 550 pages of the volume out of a total of 704 are occupied with these questions. Mr. Dreaper joins with Mr. E. Feilmann in the writing of the sections on "Dyes and Colouring Matters" and the "Analysis of Colouring Materials," while Dr. J. T. (not J. F., as is printed in two places in the title pages) Hewitt contributes the "Dyestuffs of Groups 6 to 12." These groups have been a special subject of study by Dr. Hewitt, and include the di- and tri-phenylmethane dyes, pyrone, xanthone, and fluoran dyes, indamines and indophenole dyes, azine dyes, oxazine and thiazine dyes, quinoline and acridine dyes, and the thiazole and sulphur dyes. In this section there are again some valuable tables setting out the commercial and scientific name of the dye, general characters, and reactions. The chapter on "Colouring Matters of Natural Origin" is one of the most interesting in the book, and is written by Professor W. M. Gardner, of Leeds, who is an admitted authority on the subject.

The section on the analysis of colouring materials is very carefully done, and analytical chemists will be grateful for the clear account of the methods of testing dye stuffs as well as for the somewhat extended presentation of the general reactions of dyed fibres. Over 80 pages in this section are given to tables of reactions. The chapter on "Colouring Matters in Foods" bears the evidence of American authorship, for one paragraph refers to the examination of "noodles," the meaning of which may not be clear to every English reader. It refers to a breakfast food

classed with spaghetti and macaroni. The section, however, is very complete and the information which it gives as to the colouring matters prohibited from use in foods by the United States authorities should receive careful attention n this country, where little legislative action is taken in regard to this matter. The volume concludes with a short section on "Inks," which affords interesting reading, besides some valuable hints to analysts and others.

We have represented here an immense amount of work, and great care has been taken to collect materials from trustworthy sources; the previous volumes are well succeeded by the present one.

The Diagnosis of Nervous Diseases. By PURVES STEWART, M.A., M.D. Edin., F.R.C.P. Lond., Physician to Outpatients at the Westminster Hospital, &c. Third edition, revised and enlarged. London: Edward Arnold. 1911. Pp. 477. Price 15*s.* net.

THE third edition of this well-known text-book on the diagnosis of nervous disease contains more illustrations and more material than the second edition, as it has been enlarged by about 30 pages. It has been brought thoroughly up to date by the incorporation of the latest information on such topics of present-day importance as pseudo-tumour, spinal anæsthesia, pituitary lesions, and so on. Since the appearance of the second edition three years ago the book has been translated into both French and German, a gratifying proof of the high opinion of its merits that has been formed by continental neurologists. It is not intended to take the place of larger and more ambitious text-books; its purpose is to present to the student and practitioner a compendium of neurological diagnosis, in which symptoms are described and followed out much as they would be in the actual examination of a case. It is written from an eminently practical standpoint; it is concise and readable, and the association of width of view with attention to minuteness of detail is noticeable in every chapter. In this connexion it may be consulted with advantage by the professing neurologist, since there are references to the very latest advances in diagnostic tests and methods. While the reader will not find himself burdened with unimportant and non-essential minutiæ of nervous anatomy and physiology, his perusal of the first two chapters of the book cannot fail to be instructive, for in them the author lays with adequate care just that general foundation of anatomical and physiological knowledge of the nervous system without which its pathology becomes meaningless.

We believe that this volume has been widely adopted as a text-book in different schools. There is none that can be more confidently recommended as fulfilling the requirements of student and practitioner alike, and we warmly welcome its reappearance because both of its attractive form and of its excellent and well-chosen matter.

Analyse des Harns, zum Gebrauch für Mediziner, Chemiker und Pharmazeuten, zugleich elfte Auflage von Neubauer-Huppert's Lehrbuch. Bearbeitet von A. ELLINGER, F. FALK, L. J. HENDERSON, F. N. SCHULZ, K. SPIRO, und W. WIECHOWSKI. Erste Hälfte. Wiesbaden: C. W. Kreidel; Glasgow: F. Bauermeister. Pp. 682. Price 15*s.*

THIS is practically a new book, but it is founded upon the well-known work of Neubauer and Huppert. It is the work of several writers, each of whom has devoted special attention to the branch of the subject which he has undertaken. Henderson, of Boston, has contributed the section on the physical and chemical properties of the urine, including its reaction to polarised light; Spiro, of Strasburg, has written the chapter on the inorganic constituents of urine; Schulz, of Jena, has supplied the chapter on the non-nitrogenous compounds; while Wiechowski and Ellinger are responsible for the account of the substances containing nitrogen. It will thus be seen that this, the first, part of the work deals only with normal constituents of urine, the consideration of the abnormal constituents being reserved for the second part to be subsequently published. This statement will be sufficient to show the very thorough manner in which the book has been written. The processes and tests to be employed in the examination of urine are fully described.

The references to the literature of the subject are numerous, and in most cases are given directly to the original paper in which the method was first described, so though most of them are to German articles and works, some are to English sources. For instance, the reference for the account of Moore's test for sugar in the urine is given to the article in THE LANCET of Sept. 26th, 1844. The work proves to be very complete, and the utmost care has evidently been taken to supply all the information that could be required by workers in this branch of science. When the second part is issued the whole will form the most complete treatise on urinology existing.

Veterinary Bacteriology: A Treatise on the Bacteria, Yeasts, Molds, and Protozoa Pathogenic for Domestic Animals. By ROBERT EARLE BUCHANAN, Ph.D., Professor of Bacteriology in the Iowa State College of Agriculture and Mechanic Arts, Division of Veterinary Medicine; Bacteriologist of the Iowa Agricultural Experiment Station. With 214 Illustrations. London and Philadelphia: W. B. Saunders Company. 1911. Pp. 506. Price 13*s.* net.

THE United States Government departments which correspond roughly to our Board of Agriculture spend large sums of money on researches bearing upon agriculture, and very valuable results have been obtained in their experimental stations. Whether as a result of this encouragement or not the American public appears to take an enlightened interest in the scientific side of agriculture, and a number of works dealing with bacteriology in its relation to the dairy and general agriculture have issued from the American press.
